Thank you guys for the warm welcome. I'm excited about this rig. I don't plan on parting with it. Took me a long time to find one in mint condition inside & out. I have a few questions on the tune up procedure, ALC keeps falling off, but i'll start a new thread for those questions. Thanks again.

43767. Tuning issues.

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

All, I having some issues tuning up my new to me ts820s. I'm using K4EAA's tune up procedure. Tuning into a Sinclair dummy load. I have yet to TX on the radio, due to fear of burning something up. Hear are my observations. Mode switch in the tune position, I peak the ALC with the drive knob. Once I peak the ALC, it almost immediately starts falling off. I can re-peak it with more drive, but it still falls off.

Ok, besides that. Mode switch still in Tune, meter to IP, dip the plate. Dips just fine. How you guys do this in 5 seconds is beyond me. Next: Mode switch is now in CW. Re-dip the plate. Ken says I'm looking for 225ma or so dipped on the meter. I can get it to dip at 225 ma with the load around 25% no problem. Inline wattmeter shows 100+ watts out at this time.

Now we move the meter to the RF position, Mode is still in CW. I tune with the plate control for max power output. At this time I can see 120+ watts on my watt meter. I switch the meter back to IP to check & see how far off I am from the 225ma target. around 215-220ma. Looks good. Now I switch the mode to tune to check ALC & it's DEAD. NOTHING. I can re-peak the ALC, start all over with the tune up procedure, come back & check the ALC & it'll be dead again.

Does this sound like a common problem of the Hybrid rigs? Or am I screwing something up on the tune up procedure? I have always tuned into the dummy load & my "SEND" time during tune up has never exceeded 5 seconds. I always let it cool for 10 seconds between adjustments. I'm trying very hard to go easy on it while I get the tuning part down to an art.

Thanks a bunch,
Matt

43768. Westinghouse video from 1943 explaining how tubes (valves) work.

All,
Some of you may have seen this already. I stumbled onto this video while researching VTVM's. I know it's not a Kenwood hybrid video but for the guys that think "real radios glow" and for guys just getting accustomed to their hybrids, it's very informative.

Wonder why you switch the meter to RF if you already have a wattmeter connected? The RF metering position is a relative reading and the wattmeter is a better indication of the same thing.
I would monitor plate current and the wattmeter while doing the last steps of tuneup. If you have 100 W out and 200-225 mA of plate current, STOP messing with things and operate, Try to answer a CQ or call your own. !

1. Falling ALC can be due to soft 12BY7A Driver tube. If changing Driver tube doesnt cure this come back for additional checks.

2. No need to flip to RF meter position as a last step. Your Wattmeter is better way to load. After you get your first dip in plate current in Tune mode leave meter in Ip position and then use your external wattmeter. Switch to CW mode and flip to send and alternately adjust the Plate Tune and Plate Load controls for maximum RF output of approx 100 watts without exceeding approx 200ma of plate current. (notice 200ma)

The RF meter position step was used in these rigs as in the 70s people did not have watt meters and rig had to stand alone so manufacturers starting putting the RF detector position in their transceivers.

The reason for 200ma is that the TS-820 is rated at 160 watts DC input and not 180 watts input. Page 20 of your manual tells you to load to approx 200 ma and not 225 ma which you would do for a TS-530 or TS-830 rated at 180 watts dc input. In actual practice with ICAS duty and SSB and CW modes you can load a TS-820 to 225ma and not suffer any immediate damage or any noticeable effect on tube, transformer, or HV rectifier life. However, the TS-820 design is 200ma and you will not gain anything by routinely loading to 225ma.

3. Where in instructions does it tell you to go back and check ALC or repeak the Drive? I guess you are concerned about the falling ALC indication? This is not a Class C Grid Leak bias transmitter of the 50s/60s where you have to worry about maximum grid drive current on the final tube control grids. No worry about loss of grid drive or the loading affect causing the grid drive to fall off and need to re-set drive current level frequently as you pick up more load.

In fact if you look at Page 20 you will see that it states at 200ma of plate current there may be no ALC indication. They had to state that because people (old timers) were going back and checking and trying to repeak the drive. There is a technical reason for why may be no ALC indication at 200ma of plate current but wont spend the keystrokes here.

All you need to do is peak the Drive in Tune mode once and do not worry about it after that. The Driver stage is providing RF voltage swing for the 6146 control grids. All you are doing is adjusting the driver tube plate tank circuit to resonance. The ALC peak indication tells you that you have maximum RF drive voltage which occurs at resonance.

Good to be cautious but dont obsess over 5 or 10 seconds key down time. Most important time limit is that first dip. If the Plate Tune control is not pre-set near band specific resonance (White scribed marks) when you first flip to send you could have very high plate current maybe even full scale and long key down time off resonance is hardest on the 6146s as you are exceeding plate dissipation. For that reason Kenwood gives you Tune position where Screen Grid voltage is at half normal so you cannot have extremely high plate current.

Just dont linger as you are alternately adjusting Plate Tune and Platge Load controls for approx 100 watts output into your wattmeter. As a last step adjust your Plate Tune control

to peak the output power on your wattmeter to approx 100watts. At this point plate current Ip should be close to "dip" and if Ip is near 200 ma you are done and ready to transmit.

Now need to read how to adjust Mic gain for SSB operation and how to set Car Level pot for CW operation.

Matt:

Ask yourself this:

If I have 100watts output on my wattmeter and 200ma of plate current in panel meter Ip position and ZERO ALC indication how can this be a problem? If I have no RF drive or low RF drive how could I have 100 watts output at 200ma plate current?

Does Zero ALC indication at 200ma Ip mean I have no RF grid drive to my 6146 finals? Well of course not!

So if I have 100 watts output I must have sufficient RF drive from the Driver stage even though I cant see it on ALC. YES!

What then does ZERO ALC at output and 200ma Ip mean?

Simply that you do not have positive RF drive voltage level at the 6146 control grids that exceeds the negative dc offset voltage of the operating bias.

It means with approx -55vdc operating bias on the 6146 final tube control grids(which sets your 60ma resting plate current and class of operation) that you have approx 39rms volts of RF drive or less. 39 x 1.414 = 55 peak RF volts. 55 - 55 = 0. 0 volts difference means the 6146 control grids never go positive and there will be no grid current and therefore no ALC indication. Very small grid current (30 to 40ua) causes the ALC circuit to drive the ALC bus voltage down and the ALC meter go up scale accordingly.

So at 100 watts output you have approx 39rms volts of drive or 55 peak volts of drive or 110 Peak to Peak volts of RF drive from the Driver tube tuned plated circuit you previously tuned to resonance.

39 rf volts of RF drive just isnt enough to overcome the dc bias offset so there will be no grid current and with no grid current there will be no ALC indication. However 39 rf volts is more than sufficient rf drive voltage to produce 100watts output power.

As I said in my first response you do not need grid current drive. All you need is RF voltage swing at the 6146 control grids to cause corresponding Plate voltage swing to produce current pulses at an RF rate to be applied to the Tank circuit (pi-network)as line current (I-line) which in turn causes the Tank circuit circulating current (I-circ) to continue to flow 360 degrees which in turn that RF circ current is coupled by the Plate Load capacitor to the dummy load or your antenna. ARRL Handbook, Basic Electronics Bureau of Naval Personnel, and numerous texts explain how parallel resonant tank circuits work and how a RF amplifier tube converts the HV dc Anode supply to RF.

At 100 watts dissipated by your dummy load you have approx 71rf volts and 1.4 rf amps.

Short answer is...Do not worry about no ALC indication at 200ma Ip and 100 watts output power.

If you have no ALC indication when modulating rig in SSB mode then there can be a problem which we can help you with.

Good morning Terry and group and Good Evening Dave down under.

Back about fifty treads i complained about low output on LSB.
I found that both crystal's on the PLL board were lose and re-soldered them.
Still had low output on LSB,but thought we just need to balance the carrier.
Ok, last night as i am now waiting for parts i decided to check the boards again for any lose connectors.
I took off the IF board to check it for lose connector solder joints[just give them a little wiggle] and all was fine and all with nice shinny solder joints.
Next i took off the PLL board and as you can remove it right off the rig with no problem's,i put it under my mag lamp and noticed a brown spot at crystal X2 and low
and behold there was no foil from TC2 to the jumper going to L34.
Looked like it was scraped away,or it came lose with time due to the movement of the bad solder joint at that crystal,more like scraped away.
No was not my fault when i re-soldered those crystals,as i am a very good at soldering.plus i always use solder wick,instead of a suction pump.

Don:

Not being picky but there should be no path from TC-2 trimmer cap to L34 choke. There is a path from L34 to X2 crystal. If that path was open should be no LSB oscillator signal level at all as no forward bias for switching diode D52 unless D52 is leaky? Not sure how you had any LSB carrier oscillator signal? If TC-2 path was broken would have LSB carrier output, but could not pull the xtal frequency with TC-2 to adjust the frequency response.

In any event looks like it was easy to miss when re-soldering the crystal pins. Cant imagine it being there at that time and has since disappeared. There is low current at this point.

Stranger things happen.

Just good that you found it. Not to big a fan of jumpering very many missing traces or cracked traces, but sometimes a must to salvage a board.

Don,

Just got back after a bit of holiday time.

  I have a PLL board here (out of rig) and it also has a cut trace that you noticed on yours. This seems to me to be a "post-production" modification or an error in the schematic itself. The board I am looking at here is: PLL board, X-50-1680-00, with "J25-2270-12" printed on the foil side.

Hope this helps.....cheers.........

Terry, Thank you & the other members for the reply. It's good to get definite answers for a change. I've been talking with some of the OM from the club about this same issue & I tend to get alot of "boy I can't remember" or "that was 30 years ago" answers.

I'm gonna tune it up this evening & give it a try on 20m. At least see if I can get a signal report. If I run into any more issues, you guys will be the first to know.

Thanks again,
Matt

> If I have 100watts output on my wattmeter and 200ma of plate current in panel meter Ip position and ZERO ALC indication how can this be a problem? If I have no RF drive or low RF drive how could I have 100 watts output at 200ma plate current?
>
> Does Zero ALC indication at 200ma Ip mean I have no RF grid drive to my 6146 finals? Well of course not!
>
> So if I have 100 watts output I must have sufficient RF drive from the Driver stage even though I cant see it on ALC. YES!
>
> What then does ZERO ALC at output and 200ma Ip mean?
>
> Simply that you do not have positive RF drive voltage level at the 6146 control grids that exceeds the negative dc offset voltage of the operating bias.
>
> It means with approx -55vdc operating bias on the 6146 final tube control grids(which sets your 60ma resting plate current and class of operation) that you have approx 39rms volts of RF drive or less. 39 x 1.414 = 55 peak RF volts. 55 - 55 = 0. 0 volts difference means the 6146 control grids never go positive and there will be no grid current and therefore no ALC indication. Very small grid current (30 to 40ua) causes the ALC circuit to drive the ALC bus voltage down and the ALC meter go up scale accordingly.
>
> So at 100 watts output you have approx 39rms volts of drive or 55 peak volts of drive or 110 Peak to Peak volts of RF drive from the Driver tube tuned plated circuit you previously tuned to resonance.
>
> 39 rf volts of RF drive just isnt enough to overcome the dc bias offset so there will be no grid current and with no grid current there will be no ALC indication. However 39 rf volts is more than sufficient rf drive voltage to produce 100watts output power.
>

> As I said in my first response you do not need grid current drive. All you need is RF voltage swing at the 6146 control grids to cause corresponding Plate voltage swing to produce current pulses at an RF rate to be applied to the Tank circuit (pi-network)as line current (I-line) which in turn causes the Tank circuit circulating current (I-circ) to continue to flow 360 degrees which in turn that RF circ current is coupled by the Plate Load capacitor to the dummy load or your antenna. ARRL Handbook, Basic Electronics Bureau of Naval Personnel, and numerous texts explain how parallel resonant tank circuits work and how a RF amplifier tube converts the HV dc Anode supply to RF.
>
> At 100 watts dissipated by your dummy load you have approx 71rf volts and 1.4 rf amps.
>
> Short answer is...Do not worry about no ALC indication at 200ma Ip and 100 watts output power.

Don/Joe:

That trace is a mistake in producing the boards. That is why it is cut. It was cut at the factory. Do not bridge it with a jumper wire as it would put 9vdc at junction of Xtal and TC-2. LSB carrier osc circuit must be exactly same config as USB is shown.

The small jumper wire you see is the correct path that I described earlier to forward bias diode D52. It is reflected in the Revised Edition and in the 3rd Edition of the Service Manual as a dotted line on the X-ray view of the board.

You will notice no such mistaken trace on USB carrier oscillator circuit which is identical.

I cannot say for sure if or when it was corrected. I have 4 J25-2770-12 boards here all with the mistake on them.

Don I thought you were telling us that you bridged this cut with a jumper and restored your LSB carrier oscillator.

Matt:

Even joining a club may not ensure you can find an experienced Kenwood owner. My club has lots of mostly old timers but many of them havent operated a tube rig in many years and have gravitated to mostly 2 meters and perhaps a menu driven DSP solid state final rig.

OK to ask their input, but good to have a resource like what Gordon has provided us.

I suggest that you dont live too long with ALC indication falling off under key down when loading the rig.

As I mentioned first thing to try is a different 12BY7A Driver Tube.

Make sure rig is unplugged and has set awhile. Remove just the top cover of the radio. Driver tube is located on right side of chassis on the vertically oriented RF board. It has a black metal shield can on it. You need to remove this shield to remove the tube. The shield is split along its length and wraps tightly around the tube. There is a ground strap captured between this shield and the tubes glass envelope. Take a small screw driver and spread the shield to allow you to pull it off the tube without damaging the ground strap. Install new tube and re-install the black metal shield can making sure the ground strap is on the inside. You can leave top cover off and try loading to see if different tube has corrected the fall off ALC indication.

Terry
No i did not bridge it,i was thinking about it.
I remembered seeing a board on Ebay,so i wanted to compare it first,and
then Joe confirmed it.
Waiting for a answer from Jim on parts.
This might do if he has none.

http://www.ebay.com/itm/4PCS-25V-2200UF-BC-PHILIPS-RADIAL-ELECTROLYTIC-CAPACITORS-18X20MM-AUDIO-CAPS-/140626353463?pt=LH_DefaultDomain_0&hash=item20bdfbdd37

Might be a good time to take off the RF board and check it,as it has no
forty meters signal,when i feed a signal in from my SSG.
When i last loaded the rig it arched badly and then all when silent,it
was on forty meters.

Don:

Can you find a Phillips capacitor data sheet to see what the pin spacing is?

So you are saying no RX and no TX now on 40 meters after experiencing an arc during loading the rig.

Also tried injecting 40 meter signal (7.2mhz?) into SO-239 and no RX signal.

Would be interesting to inject 7.2mhz at TP-4 and see if you have RX.

L15 tuned circuit is switched in by the RF board bandswitch deck S1-4 and is shared with the TX Mixer and RF buffer amp FET Q2.

Absent this tuned circuit you wont be able to peak the RF drive at output of the TX mixer and at gate circuit of Q2. I would think you should still be able to copy sig gen signal if you injected high enough level.

If it were me I would trouble shoot via signal injection/tracing until I found where losing it. However if it is easier for you to remove the board and perform visual inspection go ahead. Just be careful on aligning the two shafts on re-install. Have you replaced the S22 nylon coupler in the PA cage? If not, then would do that at this time.

Think it's 8mm spacing on those caps,which would be just fine.Hard to
find a data sheet,but will keep searching.
Yes i was on forty meters when the arching started and then the radio
went to sleep.
I tried my SSG on all bands,and only 40 meters did not respond.
I will try that later or tomorrow and report back.

You hit the nail right on the head Terry. Most of the guys have migrated to VHF/UHF repeaters & such. Still a great bunch of folks. They welcomed me with open arms when I inquired about becoming a ham. Any specific brand to look for when I buy tubes? I'll most likely get them from RF Parts since the club gets a little discount. They have a no-name USA made tube & a Mitsubishi listed for the 12BY7A. The Mitsu tube is a little more $$$.

I did locate the 12BY7A in the rig. One of the first things I did was take the cover off & try to familiarize myself with as much as I could. My rig has all the original tubes in it, so it very well could be time for replacements.

Matt:

I have had good success with RF Parts tubes. Probably a little higher prices than some others but no hassle returns and exchanges if needed.

No need to buy matched finals. Tubes are in parallel not push pull and no way to set bias individually.

Not much difference in 12BY7A tubes. I try to use 6146B when I can get them and also run Sylvania JAN6146Ws. Good idea to keep a set of spares on hand and perhaps to rotate them from time to time.

Don:

The other common thing to look at before you pull the RF board would be VCO signal level and frequency at TP-3 on RF board.

In 40 meter bandswitch position you should have close to 1.0rf volts @ 16mhz (see service manual for frequency vs VFO setting) at TP-3.

VCO is the Local Oscillator (LO) for both the Transmit Mixer and the 1st IF Mixer (RIF). NO VCO = no TX and no RX.

I sent a list of precision resistors and a few capacitors to a friend in the city (I live a few hours' drive outside the urban St. Louis, Missouri area). He went to a parts store ("Gateway Electronics") for me, and today shipped the results of that little shopping spree.

Basically, it was the entire parts list for a Heathkit V7a VTVM. Cost altogether, everything but a new tube, was about six bucks. A couple more dollars to mail it to me, and I should be getting all the bits by Monday.

There is also a miniature slide switch in the bag, and some diodes for making a 3-diode RF probe. I'm going to build it into a "Sharpie" marker shell, after taking out the innards and flushing the ink residue out.

The switch is it toggle the thing from a 3-diode probe to a ONE-diode probe, at need. It's a small enough slide switch to fit inside the pen body, or so I am told anyway. A picture they sent me of the switch sitting on a centimeter rule seems to bear this out.

That will make things a bit easier to deal with. I'll be converting the V7a probe connection (actually just adding a BNC fitting to the banana plugs already there) to match the one on my old O-scope. Being able to just use the same probe for multiple devices will be a help.

Another thing, for those wishing to use the 2 x 100 ohm resistors on a T-fitting, the fitting that you MIGHT want to try instead is a self-terminating Ethernet T connector, from the old 10-Base days. I have a BOX full of them, and another round dozen of the unterminated sort as well. If nothing is plugged into one of the 'legs' it is automagically connected to an internal 50-ohm terminating resistor. The stock ones are 1/8th watt units, but with a bit of ingenuity I suspect I can turn that into a 1-watt unit, perhaps 2 watts if I do the 2 x 100 ohm in parallel thing. Won't fit so neatly inside, perhaps, but ought to still work.

Look for terminating resistor plugs for that era Ethernet, as well. Those already have one of those 1/8th watters inside, easily swapped for larger.

I would never in a million years thought of terminating something like that to act as a mini-dummy-load right on the input to the scope or meter. Thanks again to the group for a nifty idea.

HI Don,

I have been following this thread since about mid way or there abouts. Well Just be careful not to bridge factory cut corrections, could end up with more troubl. From the sounds of it you are making progress and shouldn't be too long before the rig is up and running. What Terry, Mike, Gordon and some other don't know isn't worth knowing, keep up the good work and hopefully we'll hear you on the bands soon

Subject: [TS-520_820_530_830] Low output on LSB

Good morning Terry and group and Good Evening Dave down under.

Back about fifty treads i complained about low output on LSB.
I found that both crystal's on the PLL board were lose and re-soldered them.
Still had low output on LSB,but thought we just need to balance the carrier.
Ok, last night as i am now waiting for parts i decided to check the boards again for any lose connectors.
I took off the IF board to check it for lose connector solder joints[just give them a little wiggle] and all was fine and all with nice shinny solder joints.
Next i took off the PLL board and as you can remove it right off the rig with no problem's,i put it under my mag lamp and noticed a brown spot at crystal X2 and low
and behold there was no foil from TC2 to the jumper going to L34.
Looked like it was scraped away,or it came lose with time due to the movement of the bad solder joint at that crystal,more like scraped away.
No was not my fault when i re-soldered those crystals,as i am a very good at soldering.plus i always use solder wick,instead of a suction pump.

Hi Dave

A real learning experience for sure.Just glad Terry and the board has
not got fed up with me,but i am sure many
others are following and learning at the same time.
Now it's going to take a few weeks to get parts,so good time to catch up
on all that info i got from Terry.
I sure miss the days back in the 80'S when i had my 6 element Telrex 10
meter beam[long gone] and worked all those
VK's from down under.
My biggest battle right now is Arthritis,head to toe.

Cheers Dave

Don,

What I learnt years ago and forgot, the last 18 months has brought back lots and then some from being on this forum, no matter how much you know in theory, doesn't make up for actual experience or knowledge of the things that aren't mentioned in service manuals. I've had a couple of real out of the box issues and learnt so much more.

I remember the 80s cycle t'was a good one, especially compared to this one.

The knowledgable of the group don't mind spending time helping as long as one is prepared to make attempts, we all make mistakes or misread, but the support and guidance is fantastic.

Hi Group Would anyone know where the Mhz segments originate from??

Example: Where does the Mhz band segments i.e 1,3,7 (14) etc originate?

In studying the Service manual these (band segments) for the DG-1 are unclear.

Thanks in advance

Bill KB9IV

Bill:

Are you asking for a narrative circuit description of how the frequency counter works to go along with the block diagram in the Service Manual? OR

Are you experiencing intermittent 1 mhz segment display ie 1 is erratic or 3 is erratic or 7 is erratic or when displaying 14 the 4 is erratic?

If it is the latter not as simple as telling you a single IC to look at to fix the problem. Could start with reheating the pins on IC11 on Counter Board.

If you want a description of a basic frequency counter can find numerous ones via Goggle that will explain gate timing pulse, shaping the sine wave input signal to be counted to a square wave and 5 volt output, divide by 10 counting, BCD output, carry over, reset, latch, decoder drivers A thru G output etc. Some of the various freq counter makers have good descriptions to go along with the block diagrams. All of the early counters that used individual 7490, 7475 chips work basically the same.

Recognize that the DG-1 uses multiplexing so will be a little different than some of the basic descriptions you will find.

You can also download the DG-5 service manual from Gordons manual site and read the circuit descriptions as it is similar but not exact circuit.

I assume you are having a problem. If so might be better if you described the problem and someone may have a fix. Folks on here have described how to install small wires thru each of the vias and solder on each side etc as fixes for most of the intermittent display problems.

Sorry I had a typo.... "counted to a square wave" should have been "converted to a square wave".

I was trying to say briefly after amplifying your counter input sine wave you need a circuit to "convert" it into a series of Low and High logic pulses ie 0volts and 5volts that can be fed to the BCD counter chips to be counted. Typically a Schmitt trigger is used for this.

It would be nice if someone would write a description of all the counter/display circuits for our Kenwoods. I am not smart enough to do that, but sure would be handy for troubleshooting.

If you look at the DG-5 service manual it does contain timing charts and key waveforms. I have not seen a similar manual for the DG-1 ???

Andy,

Yes, the SB-200's ALC AND the RELAY terminals are used with the TS-820.

If you do not have the 820 operator's manual, go to the following link

www.n6wk.com/kenwood/

and down load the operator's manual. Go to page 15, item 16, and note how the RELAY and ALC connections are made.

Connect the SB-200 relay voltage terminal to the 820's pins 5 (Normally Open) on the 8 pin socket and ground to the 820's 8 pin octal socket pin 1 or 4.

When the 820 is keyed, relay terminals 4 and 5 will make connection, energizing the SB-200's internal relay. Switching to receive, relay terminals 5 and 4 will no longer be connected resulting in the SB-200 internal relay to De-energize.

Connect the SB-200's ALC output signal to the 820's 8 pin octal socket pin 6 and ground to the 820's 8 pin octal socket pin 1 or 4.

The SB-200's relay voltage is 100 volts. However, the 820's relay terminals can withstand that voltage so you don't need a relay interface circuit.

43799. TS520SE less sensitive on 10m?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-03 19:26:11 UTC
From: adrian.langford@ymail.com
Topic: 43799 Message: 43799

I've been aligning my 520SE this evening on receive, peaking the ANT and MIX coils for each band.

For 160-20m I can get an S9 on the meter using the internal calibration marker. But on 15m this drops to around S7 and only S5 or so on 10m band.

Is it normal for receive sensitivity to drop off like this, and I'd do why does it happen?

I just bought one of these from this vendor - but as I'm in UK postage was less!

It's a nice part and was sent well packaged almost immediately.

I soldered in a wire link to the internal VFO positions on plug. My rig came with a plug which was falling apart and held together by tape! The section with the link was intact (pins bridged by solder blob) but I wanted to treat my 520SE to a decent plug!

Assuming that there is not something electronically wrong with your receiver, it is quite normal for the S-meter readings to drop off the higher you go in frequency. The reason for this is quite easy to explain.

Your internal calibration marker is actually a harmonic generator, and as you go higher in frequency, the amplitude of the harmonics themselves, tends to drop off .

Actually, there is a very good test that you can try on your radio. On a "dead" band, listen to the background noise. Then, remove the antenna, and listen for the noise level to drop. If you can easily detect a drop in the noise level, you have adequate sensitivity to hear virtually anything that should be present on the band, and being sent to the RF amplifier stage through the tuned circuits.

This effect can even be measured up into the VHF/UHF frequencies with the proper test equipment. At those frequencies, it is called the "noise factor" of the receiver, and the desired effect is to cause the most difference between the noise the receiver produces when receiving a signal, and when it is not.

That is a rather simplified description, but should be adequate to whet your appetite to learn more about receiver sensitivity and the theoretical and practical limitations that determine it.

Plated wire-wrap wire can be an excellent tool to repair cracked walls
of through-holes and vias. Simply heat up the via, and push some
wire-wrap wire through from one side to the other while the solder is
molten. The smallest touch of rosin-core solder to the via will help
restore side to side continuity in stubborn cases.

Adrian:

It is "normal" to have some S-meter fall off on 10 meters, but that seems a bit much to me. I just looked at my TS-520 which has slightly different front end and I have approx S7 on 28.500mhz 10 meters.

Your rig has an automatic RF gain shunt attenuator circuit that reduces the gain of the receiver on 160 thru 15 meters by shunting some of the output of the Q5 RF amp thru capacitive voltage divider to ground. On 10 meters and Aux position of the bandswitch full RF output signal from Q5 RF amp is applied to the input of the 1st Rx Mixer.

If this circuit is not working you could have reduced gain on 10 meters.

This is accomplished by Switching Diode D4 and Capacitors C9/C10 tapped at the output of the Transmit Mixer Drain lead. It is tapped here because the Transmit Mixer and RF amp share the same tank circuit.

Diode D4 is forward biased all the time by 9vdc and is reverse biased by applying 14vdc to DS Terminal on the RF board. Go to DS terminal and monitor voltage to chassis ground as you switch from 15 meters to 10 meters. On 10 Meters should see 14vdc to ground. On 15 meters should see zero volts. With D4 reverse biased (turned off) you should experience full RF gain on 10 meters.

You can play with this by lifting the DS lead and using bench supply to key this circuit with low level RF signal injected into SO-239 and see if you can get change in S-meter readings.

I have seen problems with DS switching voltage due to bad bandswitch contacts and a bad D4 diode couple of times.

Now why is this circuit necessary? I have a white paper on this, but will try to give short version so dont bore anyone (although all hybrids accept the 520 have this circuit).

A multiband transceiver is a compromise rig. The TX and RX circuits share tuned circuits. For tuned circuits to be most effective you have to have correct Loaded or Operating Q. This Q is arrived at by optimizing practical values of L/C ratio for these shared parallel resonant circuits. On the higher bands like 10 there is a lot of fixed parasitic capacitance from tube interelectrode capacitance,pc foil traces, bandswitch contacts, wire leads etc. The Kenwood designers were faced with designing tuned circuits that used this parasitic capacitance. This is why you do not see any small fixed capacitors being switched in parallel with the 10 meter coil pack inductors. The parasitic capacitance must be used to form a parallel resonant circuit with less than optimum LC ratio and operating Q.

So if you have to design a multiband transceiver where would you want the performance to fall off both on TX and RX? Not on 160 or 80 but on 10 meters because it is much easier to address that loss by using high gain directive antennas which would not be so practical to build and swing on the lower bands. Easy to recover the gain on 10 meters with modest

antennas. The same is true in TX where it is "normal" to have less RF output on 10 meters due to primarily having to use the parasitic capacitance of the Driver Tube for your 10 meter plate tuned circuit. Less than an optimum tuned circuit. Antennas are used to easily address this slight TX performance deficiency.

So why do we need to have two different RF gain settings in the front end? By the way TS520 does not have this design improvement. So they set the gain of RF amp a little less hot at all times.

On low bands like 160 and 80 if you live in a urban area you can have a volt of signal at your antenna and more than one strong broadcast station in your pass band. If you run the RF amp wide open you will risk IMD being generated in the 1st RX Mixer. This IMD will cause SSB to sound like gibberish and CW signals to have phantom or ghost signals. Also poor 2 signal performance can result in de-senitizing the receiver and/or blocking if severe enough. Reducing the signal level to the 1st RX Mixer is a way to address this problem.

On 10 meters RX you are faced with exact opposite regardless of where you live. SO-239 typically sees very weak signals down in the uv level. You need Rf gain to be hot and not as much concern about 2 signal performance on 10 meters.

So fix is to reduce gain of the RF amp to the 1st RX Mixer and let 2nd Mixer run hot for the low bands (especially important on 160 and 80). Need to be able to do this without the operator of the rig having to remember to switch it so Kenwood gave you bandswitch contacts to control a diode switched RF attenuator at the output of Q5 RF amp.

So regarding your lower S-meter on 10 meters make sure you have RF-1 voltage set correctly so that AGC bus voltage is correct (some call this agc bias) and make sure that your RF shunt attenuator is working. On 160 thru 15 confirm that Diode D4 is turned on and on 10 meters make sure Diode D4 is turned off. D4 can be getting correct bias but can be failed open so need to make sure it really is switching. If D4 switch is working and RF-1 is good you probably have the best you will get out of 10 meters RX performance assuming you have done a good coil pack alignment.

If your rig was a monoband 10 meter rig the designers could have optimized the component layout and the LC ratio of tuned circuits to provide somewhat better TX and RX performance.

Sorry so long, but not easy to explain how this works in two or three sentences.

Jim:

It is not likely that the Marker signal level falling off is the problem.

Use a calibrated RF signal generator and inject 50uv or -73dBm into SO-239. A well aligned TS-520 will give approx S9 on all the low bands and on 10 meters will see something in the S7 to S6 range.

RF sig gen level is constant.

Read my post.

43806. TS-830S simple alignment query

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-03 21:46:09 UTC
From: Craig Roberts
Topic: 43799 Message: 43806

I am suffering an internal struggle between my purist and pragmatic selves.

Here's the deal. Thanks in large measure to the advice and wisdom of the gurus among you, I have restored my originally roughshod TS-830S to cosmetic and functional shininess. Well, almost.

ONE anomoly remains. On 160 meters and 160 meters only, my PLATE control pointer indication is w-a-a-a-y off at the dip. In fact, it reads 18 MHz rather than 1.8. Pointer and dip are coincidental on all other bands.

So, can I tweak the coil pack on this one band only WITHOUT screwing up all the other bands?

As much as I would wish otherwise, my current "test bench" (ha-ha) consists of an ancient but functional Sentinel Electronics, military surplus VTVM, so I really don't want to attempt a full-blown alignment of an otherwise healthy radio using inadequate equipment in order to correct a nearly inconsequential problem on a band I will probably never use.

Still -- I want it to be right.

What say you, sirs?

Terry thanks do much for such a fascinating answer - not only pointing me to solution but enlightening on transceiver design.

Of course murphy's law says I've just buttoned up the rig, put the sig gen away and reconnected things. I did at least squeeze out an S point or so with the coil pack alignment, peak WWV reception and align transformers for the 8MHz trap and IF board. Before aligning the Rx coils I had almost no s Meyer deflection on 10m so at least it's improvement. When I set rig up again for operating I heard a QSO on 10m for first time since getting the rig!

So next job will be to haul the rig back to bench and run tests you describe, starting with checking the 0V/14V control voltage for the diode. Before that will study the relevant part of the circuit alongside your description.

Thanks again and I will post back what I find.

I was using the marker signal, si will also see if the s-meter readings are different using sig gen at SO239 (it's a lovely old Racal Dana - output rock solid as frequency changes)

Terry, obviously it would be a better test to use a calibrated signal generator to check out all the bands. Of course, this is assuming a LOT to think that he might have test equipment of that caliber available. I will bow to your superior experience with these radios, but I was thinking that a few S-units drop would not be all that significant a decrease!

Just saying!

I completely agree with you Jim. Just not on the reason why S-meter indication may be lower on 10 meters. An S5 indication it is not anything to lose sleep over.

It is "normal" or "typical" to have less sensitivity unless he has problems with AGC bus voltage not set correctly (dc control voltage for the IF and RF gain controlled stages) or his RF shunt attenuator is not working properly or some other problem in the gain controlled stages. At S5 I suspect could be improved with another pass or two on the coil pack. If on my bench would make sure RF-1 was set properly and that shunt attenuator was turned off on 10 meters and do a good coil pack alignment and then check AGC threshold and button it up.

I just want him to optimize the performance to design and nothing more.

I think you and I grew up in the old Hallicrafters, Hammurlund, National tube receiver days and we lived with same affect only far worse. By even KW Hybrids standards those old treasures (which I owned many) would be considered deaf on 10 meters.

Why was this? Well very large components spaced apart with long connecting paths and tube inter-electrode capactance all contributing to a high level of fixed or parasitic capacitance that limited the designers ability to use optimum LC ratios and optimum Q on 10 meters.

One of first homebrew things many owners of these receivers built was a dual RCA Nuvistor 10 meter pre-amp. Later some upgraded to dual mosfets.

You can see this better if you look at the TS-830 RF Board schematic. You will notice there are no fixed capacitors across the tank coils for the ANT, MIXER, or DRIVER tuned circuits. They are all relying on the parasitic capacitance of the circuits and designers have played the hand dealt them and used a practical available physical size tuned inductor to allow adjusting these tanks to resonance. Just not able to optimize the LC ratio and the Q. I think if memory serves they have a 15 or 16 pf on the 18mhz tank coil. So that tells me at minimum there is that much fixed capacitance on 10 meters.

Here is article from 1961 where you can see in the introductory paragraph that authors briefly explain why sensitivity on 10 meters can be less.

http://n4trb.com/AmateurRadio/RCA_Ham_Tips/issues/rcahamtips2103.pdf

Same reason why the KW Hybrid transmit output power on 10 meters is typically lower. Having to tap down on the tank inductor so can have acceptable minimum capacitance of the air variable tank capacitor results in less than optimum Tank circuit LC ratio and loaded Q.

I have seen people saying it is due to tubes nearing upper frequency range and/or transit time and this is BS. Not at 30mhz and not with these tubes.

We all live with multiband linear amplifiers having typically lower output power on 10 meters, but seldom give much thought or discussion as to why.

A topic for another day.

Hi Jim

I was as you say using the internal marker, and take your point about weaker harmonics.

In fact I'm lucky to have found a Racal 9081 sig gen at very reasonable cost which is calibrated and holds output level from 5-412MHz!

I'm going to repeat with an injected signal. I just looked at the s readings again now I have rig back in operating position, and I'm getting S6 on market signal on 28.5MHz. I think the meter reads slightly higher when it's not upside down, as it was when I had it on bench with coil pack facing up for alignment (or maybe I was not being careful enough about parallax when reading it looking down on meter). Maybe it's not so down on 10m as I thought?

Will report back with measurements using injected signals later.

Adrian:

No need to repeat with your signal generator unless you just have burning desire to use the Racal. There is nothing seriously wrong with your rig. If there are 10 meter openings and you can copy 100mw cw beacons all is well.

Kenwood describes using the Marker and S-meter to do basic receiver alignment in the Maintenance Section of your Operating manual. This method is perfectly acceptable and can get rig working pretty well in RX and TX by following these steps. Just cannot calibrate the S-meter but if you get an S9 on 20 meters the S-meter is close enough. Only really good for making comparisons anyway.

If you want to learn how the RF shunt attenuator works and play with it someday then take cover off and do that, but for now get it on the air and enjoy!

Topic: 43799 Message: 43813

Craig,

Thanks Terry for the reference. Just need a little more information, so we can look at this common issue. When you tune the radio for 3.5 and 7.0 Mhz, where are the pointers on the plate control and load control? Reason behind this is S22 switches in padder capacitors in the PA, due to extra capacitance needed to load at these lower bands and VC1 and VC 2 do not have enough range. These are very easy to get at and usually break down because of the amount of heat from the front 6146b, (C26 22pf and C10 390pf are in parrallel, C9 100pf is in seperate wafer but subject to band will be switched in and close to this tube.

If you need I can go through the whys and hows of the load and plate air capacitors and switching in padders caps.

I'll go through the replacement procedure.

1. Remove from mains power, discharge HV, twice, I now clip an aligator lead to earth and the HV cap once discharged, while working on HV system (just remember to remove once finished!).

2. Double check the shaft coupler on Plate and Load controls, they may have slipped, if all OK then proceed

3. Remove PA cage cover and remove both 6146B, looking a the PA cage from side view, at the front of the cage S22 will have 3 caps, C10 and C26 in parrallel and C9 on seperate wafer. What I have found in the past is C10 390pf, cracks or goes out of spec with age and from heat being generated from 6146B. But check to make sure the wafer fingers are actually making contact as this could be your issue. Don't keep trying to tune radio at these lower frequencies for too long as you cause other component failures, Also check the mounting of plate and load air caps.

4. This is the part you have to decide on wheather your going to attempt to desolder the caps at the switch tag or cut, twist and solder onto the leads. Due to the tight space you must re-install the glass fibre insulation or use heat shrink on the cap leads!

You can check the capacitance of these caps and find that the 390pf will most prob be somewhere around 250pf or less, this is enough to take the pointer out of the normal range and greatly increase the amount of RF volts.

5. I, like Terry, am not a fan of just replacing components for the sake of it, but in this case I believe replacing C26, C10 and C9 is warranted.

6. The most important part is making sure you use Type 1 RF HV caps, http://www.qsl.net/i0jx/capacit.html as reference. if you don't then you'll hear sizzle, pop and the horrible smell of burnt caps and will have to start all over again. If you want I can send off forum some pictures that may help guide you. You'll need patience and time, but all in all it is not too bad an issue to repair.

7. The other 6 caps on the other side of S22 are noramlly not an issue, but still warrant insepction. So far I have only replaced these once, but the second radio I did, I didn't touch them. But that is a more difficult and time consumming repair and replacement.

Let us know how you go.

Subject: [TS-520_820_530_830] TS-830S simple alignment query

I am suffering an internal struggle between my purist and pragmatic selves.

Here's the deal. Thanks in large measure to the advice and wisdom of the gurus among you, I have restored my originally roughshod TS-830S to cosmetic and functional shininess. Well, almost.

ONE anomoly remains. On 160 meters and 160 meters only, my PLATE control pointer indication is w-a-a-a-y off at the dip. In fact, it reads 18 MHz rather than 1.8. Pointer and dip are coincidental on all other bands.

So, can I tweak the coil pack on this one band only WITHOUT screwing up all the other bands?

As much as I would wish otherwise, my current "test bench" (ha-ha) consists of an ancient but functional Sentinel Electronics, military surplus VTVM, so I really don't want to attempt a full-blown alignment of an otherwise healthy radio using inadequate equipment in order to correct a nearly inconsequential problem on a band I will probably never use.

Still -- I want it to be right.

What say you, sirs?

I have the TS 820s I notice that when I wear headphone by BOISE they cancel most of the constant background noise. does someone make a kit or product that is a Audio noise filter/blanker for consistent background noise, it would plug into the PHONE jack.

I am sure the new, solid state units must have some type of noise blanker built in like I am describing.

Thank you all

Andy N7EBG

43815. 820 acting weird after replacing driver tube

Topic: 43815 Message: 43815

I figured I would wait until I could work with someone to replace my finals, but I went ahead and replaced my driver tube today. Testing it in a contest with a contact, as soon as I transmitted, the display went to 14.992 and would not change frequencies when turning the VFO wheel. I turned it off and then back on, and I was able to change frequencies. After another transmission, though, it again jumped to 14.992 and would again not change frequencies with the VFO wheel.

I stayed on 20 meters the whole time, and I figured I would turn it off to wait until talking to you guys about it.

My next plan is to take out the new tube and put old one back in.

Many thanks, Dave.

In answer to your question, the pointer is off on the 3.5 MHz band as well. All is normal at 7 MHz and above.

Before ordering replacements (I usually deal with Mouser), I need to ascertain -- as you point out -- that these will be Type 1 RF power caps. The Vishay and TDK data sheets I have downloaded from Mouser seem to be ambiguous in this regard. Do you have any specific brand/model# caps or series of caps you recommend?

Thanks VERY much,

Craig,

I always go for the best I can afford, here in VK we have very few electronics outlets, so most of my electronics is bought from overseas, I use a lot of vishay products, but mainly stick with large manufacturers as at least I know they have a good history. When ordering, refer to the webpage that I gave and make sure the data sheets your looking at match what is explained on the webpage.

One thing you can change is the voltage rating, don't go less, but you can go higher as long as the capacitance is the same. I had to settle for a 5kv rating on one of the caps as that was all I could find at the time, was a little over kill, but it isn't going to hurt.

As for your pointers this now gives more credit to the padder caps being suspect. You'll find that 7Mhz isn't exactly the same as it use to be, but until you replace these caps you won't really notice. Make sure when you change these out you remember the previous marks, you'll be very surprised.

Keep us informed and don't forget we're here to help if you run into trouble

Fascinating reading, Terry, and I don't want to get too far afield of the main purpose that this forum exists. But it doesn't do too much harm to think about "the way it used to be" once in a while.

If you want to consider receivers that were "deaf" above 20 meters, just consider the old general coverage sets built around the "All American Five" concept, such as the famous S-38 Hallicrafters setup. Of course, that set was not much more than a table-top five tube model with extra coils and caps and a rudimentary band switch. The S-38 was microphonic as all get-out, mainly due to the stray capacitance that was rampant throughout the set, and it was amazing if you were able to hear ANYTHING above 14.3 Mhz (mega-cycles, we used to call them !) .

I was extremely privileged to possess a Central Electronics 100V Transmitter and Collins 75A-4 Receiver in my early years as a ham. How they were able to get such quality out of those early rigs amazes me, to this day!

Well, enough. I don't want to derail the forum more than I have. Thanks for the memories!

All I can say, is "FB OM" As I said, I have not had that much experience with the various Kenwoods, so I probably should have kept my mouth shut! But it certainly doesn't sound as though you have anything major, or even significant, to be concerned about !

The simplest test is the one I mentioned in my first post. If you can hear atmospherics etc. on 10 when you have an antenna hooked up, you probably have all the sensitivity that you will ever need! In the post just prior to this, I mentioned the infamous S-38 and similar receivers. Now those, were DEAF !

Alas! While tuning my TS-530S into a dummy load (quickly and carefully, as always) a "pop!" and a "flash!" signaled the death of its transmitting capabilities.
A final cage inspection revealed a cracked .01 pF 2KV cap and a burn mark on the little 6.8 uH RF choke. Accordingly, I replaced the cap, the choke and the .001 10KV cap as well, just for good measure.

Well, now I get an ALC indication in TUNE, but that's it. In normal transmit mode (momentarily) plate current is off the scale.

What blew up??

Hooray!. It was, indeed, the cathode resistors. I had doubted this because they were replaced about two weeks ago.

Of course, now I need to learn what blew them. Certainly not abuse (on my part, anyway). Flaky finals? Age? Or was it a consequence of C8's failure (cracked open).

Whaddya think?

Oh -- thanks Dave! (and Terry, of course).

Andy,

I have a TS-830 as a backup - a wonderful radio! I use a GAP HEAR IT in line module for noise reduction. Works great as I have a hearing issue. A little pricey, but I feel it is worth it.The unit requires an external 12 volt source and can be used to connect to earphones or an external speaker, as I use both at times.

Hope this might help and enjoy the hobby as I do.

Craig:

Almost 100% of time the cause of blown cathode resistors is 6146 anode to suppressor grid/cathode arc over. Approx current = 850v/5ohms = 170 amps! (This is rough calc that does not include ESR of the transformer and if you assume 5 ohms ERS you are still looking at 85 amps).

I have modified my rigs to prevent arc overs from blowing the cathode resistors. In addition to the stress on the HV caps and HV power supply you dont want to perform too many unsolder/resolder evolutions on your final board. High risk of eventually lifting a foil.

Hated to install a mod but with the 30 year old NOS 6146s tubes available to us that have set around on the shelf off gassing and experiencing several blown cathode resistors I bit the bullet and modified my rigs and no more blown cathode resistors. Also, any time you blow the cathode resistors there is high risk of damaging your panel meter.

If you do any mods I would suggest the diode string across the cathode resistors to prevent them from blowing and protecting your meter.

You can see the mod I installed on Ron WB4HFN website. Mark Gilger WB0IQK posted it there under the Kenwood Hybrid Net page under the Articles tab.

Craig,

  If I may...the MOST common reason that the cathode resistors fail is that one or both final amplifier tubes have some form of
internal "malfunction." It can be several things..internal short...etc...6146A/B/W series tubes, along with other transmitting RF tubes,
MAY test "fine" or "ok" when tested in a tubes tester...but will not function correctly in the REAL RF environment. I suggest that
you obtain some known good finals, put them in the rig and see if the cathode resistors pop. If, I have to replace popped cathode
resistors...I always have lots of extras on hand....and they pop again with the same finals...I'll replace the resistors again...and
put in known good finals. By known good...I mean...have worked in another rig without problem. Be mindful that those solder pads
on the board will only take so much...then you pull up the pad and...well you get the picture.

  Just my opinion...good luck

Thanks VERY much Wes, Joe and Terry. I will definitely install the mod. I can foresee the resistor replacement as being a recurrent inconvenience otherwise. My NOS spare finals are 35 years old and since the 6146Bs in my 830S seem to be functioning fine, I'd just as soon leave them in place (I'm superstitious, y'see).

The 530S in question apparently sat idle for a couple of decades before I acquired it -- plenty of time for the old GEs to get gassy.

Thanks again,

Craig

Understand being superstitious. Lots of opinions on best practice.

You might want to think about rotating them every year or two rather than leaving on the shelf. No better test than to put them in the circuit and for them to see the RF anode voltage swing and plate current under actual operating conditions.

I rotate mine about once a year. Have to neutralize but no big deal and it allows you to clean/inspect the PA cage and lube the fan bushings at same time.

Cooking or Gettering has no effect with 6146 tubes. I use to run my spares in a DX60 for awhile and the anode voltage swing just doesnt replicate what they see in Kenwood service. I think operating them in actual KW service conditions may be better than letting them set on shelf year after year and hope they are viable when you really need them?

After I lost two sets of supposed NOS 6146B spares in one weekend I changed how I approached it.

IMHO, it would be more than a "recurrent inconvenience", Craig. Blown out cathode resistors due to tube failures are probably becoming more and more common as good tubes become harder and harder to find. All the problems mentioned earlier would be among the consequences one would face - lifted lands on the circuit boards, additional blown resistors needing to be replaced, other components, especially the meter movement, etc. needing to be replaced. It ain't worth it NOT to put in the mod!

If anyone is worried about the mod based solely on my recommendation I can tell you that I had discussions about this problem with Tom Rauch W8JI and he helped me with the diode string across the cathode resistors and sizing of the glitch resistor.

I sized the MOVs for the Screen grid protection after looking at what Ian White G3SEK did with tetrode protection in his Tetrode Board articles. I can share the calcs if anyone is interested.

You can see what Tom had to say about Kenwood Hybrid cathode resistors here:

http://www.w8ji.com/cathode_fuse_resistors.htm

I cannot guarantee you will never blow the cathode resistors again or never incur any damage. I know more than one hybrid owner who has made this change and was previously experiencing failures and has had none since. Pretty hard to measure events that do not happen. Is the mod working or have we not had any tube arc overs? I dont know for sure and have no known bad tubes to test with.

I thought about removing the tubes and placing a jumper from the top of the plate choke to the cathode pin of the tube socket on the final board and see what happens and then I thought some more about it and went and had a cold beer!

I've been using Terrys mod in a stubborn TS-520s
now for some time with no problems. I had a 6
months period where I could not find a good set
of 6146's, and kept blowing up the cathode
resistors. Once I made the mod, it's been
perfect ever since. I also made the mod on a
TS-830s. I would not hesitate to perform the mod again if needed.

43837. TS-520 Blows Fuses - No Secondaries connected

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-04 22:34:41 UTC
From: dllewiszz
Topic: 43837 Message: 43837

Well, the old XFMR was indeed bad, and the replacement is wired according to the schematic. The DC-DC stuff is connected, but there are no secondary wires connected. As a test, I fired it up and it blew the fuse after about a half-second. (I don't have the series lamp thing built yet but guess I'm gonna have to do that this afternoon.) The fan does run for about a half second. What am I missing, and what's going on? Is the DC-DC stuff causing this? Can I remove all of that and run OK on 120VAC?

It is possible you have bad ac line filter capacitors.

Did you power transformer on bench before installing?

Did you measure xfmr Primary resistance?

Always good idea to measure the resistances of all windings and log in a notebook.

Right now with a good fuse installed if you measure resistance across your 120vac plug with the power switch turned on you should see something around 2.2 ohms.

Yeah, Andy (see below) must have fat fingered BOISE.
If you don't know BOSE audio you must play Edison shellac discs on a Victrola

I bet you are cracking a joke, aren't you, John? The noise-cancelling
headphones that I am aware of are made by the BOSE corporation.

Hello group,

I tested for and passed my Technician and General exams in the past few months and have been monitioring many of the insightful posts in this group. As the saying goes, "The only stupid question is the one not asked" here goes:

How do the front panel readings for IP and HV relate to output power? When I tune the XCVR to 2MHz I can adjust for an output of about 80W on my VersaTuner dummy load I checked the voltage across the 50 ohm dummy load and read about 170 Vp-p \ 85 Vp \ or about 60 vrms. Using E^2\R I calculate 72 W , not too far from the VersaTuner 80W reading (the scope has not been calibrated for years).

The meter on the TS-820S shows IP= 225mA and HV=780V. Are those readings in agreement with my external measurements?

I'm seeing about 4 ohms across the primaries when measuring thru the AC cord as you suggest, or when measuring on the XFMR. This is a cheap VOM so the 4 ohms may not be especially accurate.

When I look at the secondaries, I notice lower readings on the mid-group secondaries on the old XFMR, which is to be expected since it smoked and was hit by lightning.

Not sure why seeing 4 ohms unless as you say not accurate. At least not seeing bolted fault (under 1 ohm).

Are you 100% sure that all secondaries are completely open and not touching each other or to chassis ground? Do they have pig tail leads on them you have taped or no leads at all?

Can unplug the fan leads (never seen a bad fan)

Can lift the line noise caps (one end) Have seen bad caps and if bad need to replace the old disc ceramics with modern X-Y safety caps. I use X1/Y2 type.

There are a number of "opamp" filters you can build by simply searching for them on the web. I built a simple 2 stage audio filter using cheap, less than $1, LM-741 opamps.

A powered breadboard such as the one sold by allelectronics.com

http://www.allelectronics.com/make-a-store/item/PB-4060/POWERED-BREADBOARD/1.html

for $120, well worth the price!

You can also purchase the non-powered breadboard

http://www.allelectronics.com/make-a-store/item/PB-4060/POWERED-BREADBOARD/1.html

but you will have to have separate power supplies for power which include Positive and Negative supplies.

I purchased the self power breadboard and have found it indispensable when designing/experimenting with solid state circuits. I built my 2 stage opamp using single LM-741 ops amps (had quite a few of those LM-741s) using the self powered breadboard. If use a breadboard then I highly recommend you purchase the breadboard jumpers that are also sold by All Electronics. They are better than cutting solid wire then stripping the ends plus they are reusable.

Steve:

TS-820 is rated at 160 watts DC input. 780v X .225 = 168.75 watts.

Class AB1 efficiency ranges from 50% to 60% and typically we use 55%. 168.75 X .55 = 92.81 watts.

Assuming your dummy load resistor is 50 ohm non reactive then should see approx 92.81 x 50 = square root of 4640.63 = 68.12 rms rf volts across the dummy load or 192.65 P-P rf volts.

Did you measure the dummy load resistance? Common for them not to be precisely 50 ohms.

So your 80 watts indicated and 72 watts measured is low.

TS-820 should be able to easily get close to 100 watts output into 50 ohm dummy load or approx 70.71rms volts and 1.414 rf amps.

Finals may be getting soft.

OOPS! A typo. I used 750vdc for anode and not 780vdc.

780 x .225 = 175.5 dc input power. 175.5 x .55 = 96.52 watts

96.52 x 50 = square root of 4826 = 69.47 rms volts or 196.46 P-P across your dummy load.

96 watts output is more like what a TS-820 should do on 160 meters.

Again 80 watts is low.

Also as I noted in first response the TS-820 is rated at 160 watts dc input and not 180 watts like 530/830. The loading instructions state to load to approx 200ma. I know many folks who load to 225ma with no immediate or apparent long term ill effects.

Just want you to be aware of design dc input rating. I am not sure why rated at this level. 6146 final tube dissipation, power transformer VA rating, etc all factor in. Maybe just carry over from the TS-520S?

I have no idea what the original S2001A plate dissipation was as I have never been able to find an original tube data sheet. The tube dissipation would typically be the most limiting factor.

If you adhered to the dc input rating then 160 x .55 = 88 watts. 88 watts output would be about max you should load to.

Perhaps the long time TS-820 operators can comment on where they load to and their operational experience.

The "non-powered" breadboard link in my previous response is wrong. The
following link is correct for the non-powered breadboard sold at
allelectronics.com

http://www.allelectronics.com/make-a-store/item/PB-3260/BREADBOARD-3260-CONTACT/1.html

Separate positive and negative power supplies are required to use the
non-powered breadboard.

I just sold my SCAF-1. You can pick them up for around $75.00. I understand that the W9GR DSP-3 was highly rated unit. Not sure if he ever got around to making the DSP-4 model or not? Here is a list of manufacturers from Eham.

The following link shows a schematic (scroll down the page) that may fit your needs. Notice it is used with headphones. If you want to use a speaker, you can either purchase an amplified speaker or build your own audio amplifier and make it partof the filterusing the popular LM-386 audio amplifier chip. You can build a simple 2 watt audio amp using the popularLM-380 chip. They are widely available, quite often from U.S. sellers on eBay. For example, eBay ad #390443114207 is selling the LM-380 2 watt audio amplifier chip for $3.98 (shipping includedin that price)!!

http://www.qrp.pops.net/low-pass-440.asp

You can buy quad op amp chips, LM-324, from Mouser for "45 cents" each. There's a U.S. seller on eBay selling "10" LM-324 quad op amps for "$4.99" (FREE SHIPPING)under eBay ad #220664660948. That's "49 cents each", 4 cents more than Mouser BUT you don't pay shipping.

As for Perfboards for final assembly of your filter andpossibly an additional audio amplifier, are being sold on eBay.For example, 6 perf boards are currently being soldon eBay under ad #380357917556, for total cost of $9.99, shipping is "FREE" on this ad!

You can experience a lot of fun playing with these chips, changing circuit design and components, to come up with the ideal filter YOU want. Most op-amp and audio amplifier chip data sheets are availableon the web, just search for the chip's data sheet.

Sanity check: Is the 120/240 switch designed such that the center (common) contacts are on one side rather than the middle of the switch as you'd normally see in a DPDT switch? That's what I'm seeing with the ohmmeter but just want to be sure.

The wiring on the 120/240 switch had been modified by a previous owner, although the rig has been working fine. I cleaned it all up and put it back together and there is a possibility I reversed something and that's what's blowing fuses so fast. Also, I'm only seeing one of the line caps on this rig. Looks like the other one has been removed.

Thanks for the advice!

Do you have the 520 service manual schematic? If you do not then I recommend you download it from Gordon's website

n6wk.com/kenwood/

The 520 service manual schematic will answer your question.

I do have the full service manuals for the 520 and the 520S -- and I've just discovered that the 520 schematic differs from the 520S wiring in the Primary side of the XFMR and the 120/240 switch. The manual doesn't really tell me about the internal construction of the 120/240 switch, but the ohmmeter confirms that the center/common is not physically in the middle of the switch. That aside, a close reading of the two schematics reveals the 520S schematic more closely matches the wiring on my old 520, and the 520 schematic is different! I'll rewire according to the 520S manual and report back here with results. (Surely there's a tech note out there somewhere about the error in the 520 schematic?)

43855. TS-820 question

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-05 14:32:27 UTC

Topic: 43855 Message: 43855

Hello all,
New member here and somewhat new to the 820 (had one back in the 80s). I just picked up a "deal" on the 820 and thought I'd bring it back to standards and life. The rig hears well, looks ok but just doesn't transmit. I have made sure the heater switch is on, replaced the driver and both finals but no meter reading for output. The HV reads ok so I don't think there is a transformer issue. Any suggestions as to where to start looking(what board)? I have noticed that when keyed (cw) the meter jerks for a second in the opposite direction.
Thanks for any suggestions and I appreciate any help.
73,
Ted K8AQM

I don't see any difference between the TS-520 and the TS-520S primary voltage switch. Both TS-520/TS-520S primary voltage select switches are "DPDT" and both are wired the same. I may be missing something here so where are you seeing the difference in the voltage select switch wiring between the 520 and 520S on the 2 schematics? I don't see any difference.

I am really confused here over a somewhat simple issue. First off, check the position of the switch. Second, just how hard is it to solder two or three wires from a primary to a switch that had the same wires on it from another transformer? Try taking the wiring off altogether and apply power. Normally they use the outer as 220 and one end and center tap for 110. Try putting a cord with a fuse in line direct to the transformer and see if it blows the fuse. I do not have a schematic in front of me, but it does seem fairly straight forward. Just what size fuse are you using? Brad KB2CHY

Andrew,

Check out the SCAF-1 filter by LogiKit. I built one and am happy with its performance in reducing much of the background hiss I normally experience with my TS-520S and full wave loop antenna. It goes between your radio audio output and external speaker or headphones and is adjustable.

73,

Mac K6OVI

Sorry for the TYPO, BOISE instead of BOSE headphones

All jokes aside, Does any one have suggests for an external audio filter
to cut out the background noise.

Something like modern radios have as standard.

43859. Source for Type (or Class) 1 padder caps??

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-05 16:06:17 UTC
From: Craig Roberts
Topic: 43799 Message: 43859

It is apparent that I need to change the padder caps on the bandswitch wafers in my TS-830's finals cage.

These ceramic discs need to be of the type 1 dielectric RF power capacitor variety in these values:

22 pF 3KV
100 pF 3KV
390 pF 3KV

Has ANYONE found ANY source on this planet for such devices??? I can find type 2 caps with X7R or Y5Pdielectrics easily but, I am told, they will self-destructively snap, crackle and pop. These are, in my experience, unwholesome and unwelcome noises leading to discouragement and inconvenience.

Thanks,

Craig
W3CRR

If you are talking about the "hash" type background noise then the active and passive audio filters you can build that I am familiar with wont be too effective on SSB as this noise is high frequency. These kinds of filters are typically more effective on CW and depending on what you build may result in some loss of gain and ringing.

Your TS-820 already has a audio circuit that is switched in CW mode to tailor the audio response. You can of course also run with reduced RF gain and not miss too much if have a good antenna.

Very hard to beat the new DSP noise reduction systems. Your audio output is converted to digital signals and then processed. It is amazing how well these work, but at a pretty steep price compared to the simple active and passive designs you can build.

You can go to You Tube and listen to demos and on the DSP filter manufacturers webpages they often have sound bites to let you listen to SSB and CW signals with the filters switched in and out. Search on DSP-599Zx and Gap and will find others as well.

Here is the Gap DSP speaker demo. Very dramatic difference switched in and out. Can hear some distortion, but a lot less fatiguing to listen to.

Simple math.
Provided on the Rig's final stage metering are , roughly the voltage and current for the final tubes plate circuit .
I x E= DC Wattage.
 DC power Watts x Efficiency percentage = RF output power..
.225A x 780V = 175.5 W DC x 50% = 87.75 W. RF .
If you only are getting 72 watts on your Wattmeter,
This means you have gone too far with the loading capacitor and have passed your most efficient point in the tuning process. OR not completely dipped your plate current with the plate tuning capacitor and are out of resonance in the PI network.

Subject: [TS-520_820_530_830] TS-820S Load Power

Hello group,
How do the front panel readings for IP and HV relate to output power? When I tune the XCVR to 2MHz I can adjust for an output of about 80W on my VersaTuner dummy load I checked the voltage across the 50 ohm dummy load and read about 170 Vp-p \ 85 Vp \ or about 60 vrms. Using E^2\R I calculate 72 W , not too far from the VersaTuner 80W reading (the scope has not been calibrated for years).

The meter on the TS-820S shows IP= 225mA and HV=780V. Are those readings in agreement with my external measurements?

Topic: 43862 Message: 43862

The Saturday's net on 40 meter we had 18 stations checking in under good band conditions. We had 6 new check-in, W3CRR, WG4VSP, K2OCW, KC9QPM, W2KS, and W8IJL. Out of those, there was:

2 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
5 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 16 stations checking in under good band conditions. We had 7 new check-in, KD5IFN, W0TI, K5HSG, K5GJB, NM5GB, N0NEM, and W5AKS. Out of those, there was:

4 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
3 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39

April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 45, Sunday's total = 50
June 2013, Saturday's net total = 30, Sunday's total = 27
July 2013, Saturday's net total = 63, Sunday's total = 41
August 2013, Saturday's net total = 18, Sunday's total □ 16 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Alslo , listening to CW with a SSB width filter is inviting hiss and other noise into the audio. Many ops buy without the optional CW filters to save a few bucks or don't anticipate wanting to get on CW.

The switches are the same indeed, but the schematic wiring in the two manuals is definitely different. I'll have to scan those portions of the schematics and expand and mark them to show the differences. Look closely at your schematics and note the way the wiring changes from the 520 to the 520S around the DPDT switch and the way the two primaries are setup. It'll be interesting to see if my problem disappears after I rewire according to the 520S. I removed the old wiring from the switch because it was messy and had been removed/replaced somewhere along the way. Following the 520 schematic seems to be what was blowing my fuses on the primary.

The manual doesn't really tell me about the internal construction of the 120/240 switch, but the ohmmeter confirms that the center/common is not physically in the middle of the switch. That aside, a close reading of the two schematics reveals the 520S schematic more closely matches the wiring on my old 520, and the 520 schematic is different! I'll rewire according to the 520S manual and report back here with results. (Surely there's a tech note out there somewhere about the error in the 520 schematic?)

If the transmitter's 780VDC HV and 225ma IP current indications are correct, the 820S DC input power is 175.5 watts (780 x .225 = 175.5).

Since the 820S final amplifier operates in Class AB1 which has a typical efficiency rating of "55%", this would result in an output power at the 820S's antenna SO-239 connector of 96.5 watts (175.5 x .55 = 96.5 or 175.5 - 45% = 96.5) which is normal for a TS-820/820S.

Watt meters tend to fool us from time to time. If the components in the metering circuit are good, within tolerance, and the voltages are correct, then those should be used to determine the input and output power rather than a watt meter. Most watt meters have a percentage of error (see the watt meter's specifications) that must be considered when viewing the meter.

The typical efficiency rating of a Class AB1 amplifier, with all factors operating correctly, is "55%".

I just printed the TS-520 and TS-520S schematic portions that show the primary winding and voltage select wiring. I looked at them closely and I do not see any difference in the switch wiring. The only difference is the "Fan" wiring in the 520S wired directly to only one of the primary 0/100 windings but in the 520 the fan is wired through the 12 pin socket but still between only one of the 0/100 primary windings.

> The switches are the same indeed, but the schematic wiring in the two manuals is definitely different. I'll have to scan those portions of the schematics and expand and mark them to show the differences. Look closely at your schematics and note the way the wiring changes from the 520 to the 520S around the DPDT switch and the way the two primaries are setup. It'll be interesting to see if my problem disappears after I rewire according to the 520S. I removed the old wiring from the switch because it was messy and had been removed/replaced somewhere along the way. Following the 520 schematic seems to be what was blowing my fuses on the primary.

I may be missing something here so where are you seeing the difference in the voltage select switch wiring between the 520 and 520S on the 2 schematics? I don't see any difference.

The manual doesn't really tell me about the internal construction of the 120/240 switch, but the ohmmeter confirms that the center/common is not physically in the middle of the switch. That aside, a close reading of the two schematics reveals the 520S schematic more closely matches the wiring on my old 520, and the 520 schematic is different! I'll rewire according to the 520S manual and report back here with results. (Surely there's a tech note out there somewhere about the error in the 520

schematic?)

Additionally,
The cathode current where the Kenwood meter is connected also includes the screen current, so that is not part of the plate current we need to consider.

Sent: Monday, August 5, 2013 2:53 PM
Subject: [TS-520_820_530_830] Re: TS-820S Load Power

If the transmitter's 780VDC HV and 225ma IP current indications are correct, the 820S DC input power is 175.5 watts (780 x .225 = 175.5).

Since the 820S final amplifier operates in Class AB1 which has a typical efficiency rating of "55%", this would result in an output power at the 820S's antenna SO-239 connector of 96.5 watts (175.5 x .55 = 96.5 or 175.5 - 45% = 96.5) which is normal for a TS-820/820S.

Watt meters tend to fool us from time to time. If the components in the metering circuit are good, within tolerance, and the voltages are correct, then those should be used to determine the input and output power rather than a watt meter. Most watt meters have a percentage of error (see the watt meter's specifications) that must be considered when viewing the meter.

Subject: [TS-520_820_530_830] Source for Type (or Class) 1 padder caps??

It is apparent that I need to change the padder caps on the bandswitch wafers in my TS-830's finals cage.

These ceramic discs need to be of the type 1 dielectric RF power capacitor variety in these values:

22 pF 3KV
100 pF 3KV
390 pF 3KV

Has ANYONE found ANY source on this planet for such devices??? I can find type 2 caps with X7R or Y5Pdielectrics easily but, I am told, they will self-destructively snap, crackle and pop. These are, in my experience, unwholesome and unwelcome noises leading to discouragement and inconvenience.

Thanks,

Craig
W3CRR

I dont agree. We are doing back of envelope calcs here.

I never school anyone to subtract out the SG current and make precise calculations. I dont even care if they know it is cathode current or not and how different than plate current. The Operating manuals tell you to set the resting plate current to 60ma they dont tell you to calculate and adjust for the SG current component. They tell you to load to 200ma IP (plate) current. They dont tell you to adjust for the SG component.

These are Kenwood rigs and not Yaesu rigs. You wont see IC on the panel meter.

When Kenwood states 200ma for the TS-820 or 265ma for the TS-830 they are talking about the IP position of the rigs panel meter. They dont expect the owner to know or understand that it is really displaying Cathode current and that you can load the rig 24ma higher.

This ensures if owner loads to the operating manual specified IP limits then they are never in any danger of exceeding 6146 plate dissipation.

Yes for precise calculations would have to take SG current in to consideration, but back of envelope calcs is all we need. Same as using 55% for Class AB1 efficiency. We dont really know what the efficiency is. Same as we dont know what the Pi-network losses are per the given band. Are they 2% or 6%?

What we do know from experience with good tubes, good coilpack and TIF alignment, and spec DC voltages it is typical to be able to get very close to 100 watts output into a 50 ohm dummy load at the recommended IP which we all refer to as Plate Current and not Cathode Current.

If this fellows TS-820 is getting 80 watts output on 160 it is nothing to lose sleep over, but a TS-820 in good trim can do better.

RE: " I remember reading there was a way to check for proper signals into the mixer board."
I surely wish someone could publish ALL the correct input frequencies and signal levels for the DG-1 mixer and also the complete adjustment procedures for the circuits within it. I have researched internet and this site in particular for 'DG-1' display and came away with the cleanest connectors ever after about 862 posts read.
I started with a DG-1 that was totally inop in 2 separate radios. The second DG-1 works fine on either radio. After weeks of strained eyes and resoldered joints the DG-1 reads 88.000.0 on WWV up to 14. 14MHz up to 29.5 reads 99.000.0. If anyone has or knows of the values I should see at the 5 test points or the alignment procedure It seems it would be of a great value to be posted here on this site with all of the posts I have seen here about the DG-1 in particular.
I would like to commend all who take their time on this Group, good job guys! Even in the short time I have been a member I have found the info to get one of my 3 radios (820,820S,820D) down to a 5-15 cycle(Hz) drift over several hours. Way below factory spec. Thanks in advance for any light that may be shed on the DG-1 project.

I may have a very old 520 schematic that has been updated and replaced - perhaps many years ago. Mine is a foldout in a full printed manual with the code number 33912 printed on the back. (Figure 38 in my copy) I haven't downloaded one from an online source, but am just comparing the two printed manuals in my hand. The switch wiring is definitely different on the 520 schematic and when I draw it out I can't see any way it would work. I need to download a copy and compare.

I have now wired my rig per the 520S schematic and am now seeing the 2.2 ohms across the AC line cord. This is because it is now wired correctly -- at least that part is wired correctly because the two primaries are effectively in parallel. When I was seeing 4 ohms, that was because I was wired per the 520 schematic which didn't allow the other primary to be in line correctly.

So, I fired 'er up and I had lamps for about one second, then poof, the 6A fuse blew. Not as fast as before, but still blew. I've double and triple checked my wiring and see nothing that should cause the fuse to blow -- no secondaries connected, but the DC-DC stuff is still there. Guessing I should isolate that completely by disconnecting it also for another test.

I'll have to scan those portions of the schematics and expand and mark them to show the differences. Look closely at your schematics and note the way the wiring changes from the 520 to the 520S around the DPDT switch and the way the two primaries are setup. It'll be interesting to see if my problem disappears after I rewire according to the 520S. I removed the old wiring from the switch because it was messy and had been removed/replaced somewhere along the way. Following the 520 schematic seems to be what was blowing my fuses on the primary.

The manual doesn't really tell me about the internal construction of the 120/240 switch, but the ohmmeter confirms that the center/common is not physically in the middle of the switch. That aside, a close reading of the two schematics reveals the 520S schematic more closely matches the wiring on my old 520, and the 520 schematic is different! I'll rewire according to the 520S manual and report back here with results. (Surely there's a tech note out there somewhere about the error in the 520 schematic?)

Topic: 43840 Message: 43878

OK I just loaded my personal TS-820S in good trim with pair of 6146B tubes @ 2.0Mhz.

Loaded to 100 watts output indicated on a Drake W4 wattmeter into 50 ohm dummy load. Measured the RF voltage across the 50 ohm resistor with calibrated Boonton 92E to be 70.65 rf volts. Panel meter readings were HV= 805vdc and Ip= 225ma (as well as can interpret these values from the panel meter graduations).

70.65 x 70.65 = 4991.42/50 = 99.83 watts

805 x .225 = 181.13 watts. 181.13 x .55 = 99.62 watts

805 x .204 (Ip minus 20.60 ma SG current measured with BK2712 DMM) = 164.22 watts. 164.22 x .55 = 90.32 watts or 164.22 X .60 = 98.53 watts.

So using Cathode current and 55% efficiency output power should be 90.32 watts. What gives?

So which DC input power calc and Class AB1 efficiency should we use?

Also how accurate are the HV and IP readings. Dependent on the accuracy of the cathode resistors and the HV voltage divider resistor string. Probably at best 5% accurate with new resistors.

In practice all these calcs are academic and hope new owners and newly licensed come to understand them in time, but in the mean time no need to understand them or be able to perform to tell if their rig is operating to "normal" output power.

This is why I like to load using calibrated external wattmeter into 50 ohm non-reactive load. Besides being faster, easier, less stress on finals it tells me when things look right. Can of course use the RF sniffer relative power position of the panel meter, but why not put an actual output power number to it. Easy then to immediately see if things look "normal".

Again to the fellow who asked the question it was not a dumb question and you can see that measuring and calculating the DC input power may or may not equate to the measured rf output power. Several reasons why this occurs which takes too many strokes to explain here including why plate current dip does not always occur at max RF output. Tuning tank to max output power = max tank impedance = max RF voltage swing. This does not always occur where the tank is resistive (resonant)using the old fashioned dip and load method. Tune to max Rf output power without exceeding Kenwoods recommended IP ratings for your particular model.

If you ever graduate to a grid driven tetrode/pentode high power linear amplifier you will learn why your manual list the meters of importance in the loading sequence:
1. Screen Grid Current
2. Control Grid Current
3. RF Output Power
4. Plate Current

Notice where plate current meter is in the pecking order. I dont know of too many amp manufacturers who say much about this meter other than dont exceed 700ma or whatever the max IP is.

Terry K9TW

43879. Re: TS-520 Blows Fuses - No Secondaries connected

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

Topic: 43837 Message: 43879

And the answer to the question I've been posing along the way is "YES" - the DC-DC stuff can cause fuses to blow when everything else is disconnected!! Pulling the leads from the terminal block, I powered up and had lamps steadily. Then I reconnected the secondaries, did the same, and still looks good. Connected the speaker, tuned WWV, stuck finger in SO239 for antenna, and had the signal.

If I don't intend to use this rig on 12VDC, is there anything I'll miss by having these transistors off line? That may be my preferred course of action rather than replacing one or all, whichever is shorted and killing the rig.

As a test, I fired it up and it blew the fuse after about a half-second. (I don't have the series lamp thing built yet but guess I'm gonna have to do that this afternoon.) The fan does run for about a half second. What am I missing, and what's going on? Is the DC-DC stuff causing this? Can I remove all of that and run OK on 120VAC?

Good job finding the source of the problem.

I did a check for replacing the 2N4049 and couldn't find the direct replacement but did find the NTE replacement which is an NTE-28. NTE doesn't give their prices, you have to use their RFQ link on their website. Mouser does not sell them, Newark doesn't have them in stock but their price for one is "$111.00". However, "Arcade Electronics" has them in stock for "$110" each.

http://www.arcade-electronics.com/NTE-28-p/nte-28.htm

That's a lot of money to pay for a transistor.

43881. Padder caps -- a confession

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

Ummm.

Okay, yesterday I pleaded for information about where to obtain disc ceramics suitable for use as padder caps on my TS-830S's final amp cage bandswitch wafers. The would-be replacement of the original 3KV C9 (100 pF), C10 (390 pF) and C26 (22 pF) was to realign the plate current dip point on the 160 and 80 meter bands to coincide with the front panel pointer markings under the PLATE control.

Well, as it happens, there is no need for new padder caps after all. There IS a need for me to pay more attention to front panel silk screening. Y'see a very highly respected Kenwood hybrid guru known to us all responded to my plea, very politely pointing out that the silk screened arcs relating to the two lowest bands were actually quite wide. On 160, for instance, the "dip arc" ranges from 9 o'clock to nearly 3 o'clock and was not restricted to that little portion marked "1.5".

Sure enough, my plate current dips fall well within the limits on all bands.

I relate this somewhat embarrassing "mea culpa" for the benefit of fellow hybrid newbies. I'll take the shame bullet for ya, fellas.

Oh, incidentally, Mouser has suitable caps. They're the 3.15KV SL rated ones made by Murata. I had to have that pointed out to me, too.

Well, I can be excused. I've been a ham for only 43 years. I'm still learning.

73,

Craig

I dont agree. We are doing back of envelope calcs here.

I never school anyone to subtract out the SG current and make precise calculations. I dont even care if they know it is cathode current or not and how different than plate current.

Yes for precise calculations would have to take SG current in to consideration, but back of envelope calcs is all we need. Same as using 55% for Class AB1 efficiency. We dont really know what the efficiency is. Same as we dont know what the Pi-network losses are per the given band. Are they 2% or 6%?

What we do know from exper
If this fellows TS-820 is getting 80 watts output on 160 it is nothing to lose sleep over, but a TS-820 in good trim can do better.

It isnt about a "few" watts.

80 watts output vs 100 watts output for the same DC input power is 20% low. I would be interested in understanding why any parameter in my radio was off by 20%.

Is it the radio or is the measuring device or measuring technique?

Anyone who has a service bench regardless of how modest or sophisticated is faced with that question. Measuring technique and accuracy is important. Not hard to be fooled into thinking something wrong when it was a measuring error.

The fellow did exactly as he should have and measured with a wattmeter and by measuring RF voltage with an O-scope and applying the math. He had the knowledge of how to make the measurement with his O-scope and how to make the conversion from P-P to rms and to wattage. Makes me smile.

This is a technical hobby, a questioning mans hobby, and a thinking mans hobby.

We all know 80 watts makes little to no difference on the receiving end. However, if you had a new hybrid and it only put out 80 watts would you take it back to dealer and ask for another one or not worry about it? What the heck is a "few" watts.

With an older in service rig when would you investigate and want to return it to its former design spec performance?

I think when it appears that power is down 20% might be good time to think about looking into it. Might be as simple as low emission finals?

Everyones definition of "few" is different. Everyone has different quality standards. Everyone has a different definition of acceptable performance.

I see lot of radios that owners have been living with workarounds for a long time and some have no idea it wasnt working correctly.

Craig,

Your "confession" only highlights a general problem on email reflectors. I and likely several others should have responded to your problem by suggesting that you you look at the arc on the final control and the different widths of each band. But based on reactions on many reflectors of being flamed for "stupid suggestions", I didn't give a common sense reply. I have certainly made the mistake you did, and MANY other similar errors several times over my 40 years of hamming. I just think that we are indeed "amateurs", hopefully constantly learning, not "professionals" doing this for a living.

Thanks for having the courage to remind us to look around for the simple first.

Topic: 43702 Message: 43886

I'm not very familiar with the alignment procedure of the DG-1, but I do recall having to peak a signal with two coils although the peek to peek voltage of the test point was WAY above what the service manual called for...I got something like 1 volt from my DG-1 where the manual called for 180mv. I just adjusted for the maximum voltage and called it good.

I still have to replace the temporary choke with the proper value part, I can take some notes on the input values (freq and voltage), and take some captures with the digital storage scope so you can see what the wave forms should look like.

Subject: Re: [TS-520_820_530_830] Re: TS-520 Blows Fuses - No Secondaries connected

Good job finding the source of the problem.

I did a check for replacing the 2N4049 and couldn't find the direct
replacement but did find the NTE replacement which is an NTE-28. NTE
doesn't give their prices, you have to use their RFQ link on their
website. Mouser does not sell them, Newark doesn't have them in stock
but their price for one is "$111.00". However, "Arcade Electronics" has
them in stock for "$110" each.

http://www.arcade-electronics.com/NTE-28-p/nte-28.htm

That's a lot of money to pay for a transistor.

Thanks for the link. I'm not the one with the DC to DC converter.
However, I'm sure wizz will notice the link.

Many types of Resistors go high in value as they age. Maybe checking for low voltages in final screen and driver supply lines would help track down 20 % shift in output ?

Subject: [TS-520_820_530_830] Re: TS-820S Load Power

It isnt about a "few" watts.

80 watts output vs 100 watts output for the same DC input power is 20% low. I would be interested in understanding why any parameter in my radio was off by 20%.

Is it the radio or is the measuring device or measuring technique?

Anyone who has a service bench regardless of how modest or sophisticated is faced with that question. Measuring technique and accuracy is important. Not hard to be fooled into thinking something wrong when it was a measuring error.

The fellow did exactly as he should have and measured with a wattmeter and by measuring RF voltage with an O-scope and applying the math. He had the knowledge of how to make the measurement with his O-scope and how to make the conversion from P-P to rms and to wattage. Makes me smile.

This is a technical hobby, a questioning mans hobby, and a thinking mans hobby.

We all know 80 watts makes little to no difference on the receiving end. However, if you had a new hybrid and it only put out 80 watts would you take it back to dealer and ask for another one or not worry about it? What the heck is a "few" watts.

With an older in service rig when would you investigate and want to return it to its former design spec performance?

I think when it appears that power is down 20% might be good time to think about looking into it. Might be as simple as low emission finals?

Everyones definition of "few" is different. Everyone has different quality standards. Everyone has a different definition of acceptable performance.

I see lot of radios that owners have been living with workarounds for a long time and some have no idea it wasnt working correctly.

I could point out that the freq range spread on 160M is 10 %,
 80M is 12.5 %,
and on, for instance,
 12 M it's only 0.4 % of the frequency.

Here is a fine web page showing a BC1-T from scrap heap to total restoration. You will see a set of four 833s in full glory as you scroll down the page. Sorry to derail the thread, again, but it is just too much FUN to look at these pictures, and remember when. And also to praise those fellows who have the time, patience and talent to take on such a task. Admirable !

Terry,

Your post and those of John Davidson, Wes Will and Jim S, have provided some interesting ideas and facts - and I am greatful for the info.

I continued to run tests in my lab (the garage) to try to determine which meters I can rely on - if any. Seems with frequency and temperature changes the electronics (passive and active) perform somewhat differently. For example, the DUMMY LOAD resistor in the MFJ shows about 15% difference in resistance (42 ohms cold, 48.4 ohms hot) that would cause a little over 15% difference in computed output power (100^2 \ 48.4 vs 100^2 \ 42).

I will use the data I have gathered, along with the groups input, to compare to data after replacing the driver, replacing the PA tubes and equalizing.

Thanks again for the support. Your recent and past posts provide a wealth of info for new hams like me - something not available at school, in the books or even on GOOGLE (HI HI).

Kind Regards,

Steve

Thanks Deiter, You are right on as it calls for 0.1v-0.2v and mine measured 2.60V. The coils T1 & T2 had no effect on the voltage adjustment at all. I have resoldered so much I started looking for a shorted trace or ?? Am going to try the first 103 cap in the circuit tomorrow as it acts like it is high resistance but it's still on board. Would appreciate any thing you might forward as once I get this voltage down I see no other help in the manual so far as other voltage specs or adjusting T3 & T4.
Actually what I do know at this stage is the 1 meg crystal is working and adjusted correctly. I spent most of this evening making sure all volts and freqs to the mixer connector were present and adjusted to spec from the radio so I could consintrate on the DG-1 and not keep rechecking radio specs. Thanks for the response.

Steve:

I am not familiar with the MFJ dummy load. All dummy loads have a duty cycle and a de-rate curve. Also the internal resistors will have a tolerance, but not common to see it listed. I think the replacement ones in MFJ catalog have tolerance of 10%.

My Heath Cantenna with original carborundum (carbon film on ceramic rod)oil immersed resistor measures cold at 49.6 ohms.

My CelWave 250 watt dry type measures 50.3 ohms.

I have never measured them after "heavy" use.

You might look in MFJ manual to see if it has derate/duty cycle curve and resistor tolerance specs listed.

You can perform Driver Tube test by placing SG off, rig in CW, heaters on, flip to Send, peak the drive and set the ALC indication to exactly full scale with the Car Level pot and leave keyed a few seconds. Should be able to get full scale deflection (FSD) and stay there without drifting off. Leave keyed for a few seconds. Do this on all bands and let 12BY7A rest a minute or two between each band. Should get FSD that does not drift off with Car pot between 0900 and 1200 max. If you can do this nothing wrong with driver tube.

First you cannot have 2.6rms rf volts at TP-2. I suspect you are measuring Q3 DC emitter voltage?

All TP measurements are RF signal voltages.

I have been on side lines hoping an experienced DG-1 person would jump in. Perhaps all on vacation? I am not an expert. I will give you readings from my notes. All measured with Boonton 92E. Can measure with standard RF probe and VTVM/DMM or O-scope and convert to RMS:

You need the following inputs to the Counter Mixer board:
1. DC power 14vdc and 5vdc
2. 9vdc diode switching bias voltage for LPF B1-B4 (8.4vdc)
3. Carrier Oscillator CCR
4. VCO Oscillator CVC

Suggest you make sure you have correct Carrier Osc input to IF board first. This is commonly mis-adjusted as Service Manual says to set to 50mv. This is wrong. CA-2 should be 300mv. Then adjust for 100mv to 150mv CCR level at Pin 7 Counter Mix board connector.

Next make sure you have good VCO level at Pin 1 = 900mv

Here are approx RF signal levels (rms) from my notes working backwards from Cin output:

1. Cin Output to the Display board = 1.0v
2. TP-5 Output of low pass filters and input to wide band amplifier = 200mv
3. TP-4 Output of Mixer IC1 adjusted by T3 = 270mv to 300mv
4. TP-3 RF Input to Mixer IC1 = ? I dont see this listed.

What I do have is the actual RF input level at Pin 11 of IC-1. Measure Pin 11 to floating ground Pin 4 = 10mv to 30mv of VCO signal. I also have LO input to Pin 5 measured from Pin 5 to Pin 4 = 210mv.

5. TP-2 Carrier Oscillator 7.830 Mhz (LO) = 220mv adjusted by T1/T2.
6. TP-1 1Mhz clock = 200mv (same for CL-1)

Hi Terry,
First let me say Thank You! I copied and pasted this post for safe keeping. Have been trying to compile a Service Manual with correct info. This has been frustrating to say the least as I make a correction only to find it too is incorrect. :>D IE the car osc volts?
This Group has been invaluable in correcting such things as the RF Speech Processor alignment and such. I have to go out of town on family business but anticipate better results when I get back and can settle down to some good trouble shooting with the voltages you have posted here. I have an 820, 820D, and a 820S all operative. The 820 has run 24-7 for almost a year with good receive and excellent audio reports. (Kenwood audio U know!) Enough, Again thks
very much and hope to be back on here in a week or so with a better report or at least with less doubts:>(

OK Jim:

I just thought when I saw you state T1/T2 had no effect on the signal level at TP-2 and that you had 2.6volts that you might be taking DC voltages and not RF signal voltages.

When troubleshooting it is always best if a unit will power up to perform ac signal tracing/signal injection and when you find the signal is low or missing then revert to dc voltage measurements at the active devices (transistors, mosfets, ICs). Kenwood did pretty good giving us the CBE and DSG voltages and they did pretty good giving us the required "goes-ins" and "goes-out".

In my experience the Counter Mixer board seldom has any failures of active devices and the service manual gives a pretty good block diagram so you can figure out the mixing scheme. So if you go to the chart on Page 73 you will see the frequencies you should have at Cin at each band switch position. Just place your rf probe/scope and freq counter there and flip thru the bandswitch and should see these frequencies and approx 1.0rms rf volts level (may vary a little around 1.0 volts). Then go to the Counter board and repeat to see if Cin path between the two boards is good. Can also go to IC5 pins 12 or 13 and validate that you have Cin there. Just be careful measuring on pins of ICs not to slip and short them.

Yes something really bad happened with the development of the 820 service manual. It has taken me years to mark mine up and take notes and probably havent found all the problems. Worse case is when it provides the wrong test point, wrong adjustment point, and wrong acceptance criteria in same step.

If you have some missing signals at Cin then go to B1-B4 and make sure you have 8.4vdc diode switching voltages being provided by the bandswitch. The chart on pg 73 shows you which frequencies are involved with B1-B4 under LPF band column.

Terry,
Well, I am an experienced DG-1 person, but no expert. I have worked on these things until I am blue in the face. We have gotten to the point that if they come in working, we do not even open them when doing a recap. Disturbing the board at all can lead to problems. If they don't work...

IT IS ALWAYS A COLD SOLDER JOINT. Troubleshooting is a waste of time, in my opinion. I suppose if you can trace down the problem, it might tell you where to do some more soldering. When you look on the tops of the boards, some pads appear to have no solder whatsoever. A wonder that some of them ever worked at all. I don't know if the holes are through plated or what. Resolder everything on top that you can get to. This has eventually fixed everyone so far. When you test it, be sure to screw the boards down to the case and the case to the chassis, as the ground is important.

Jim:

Yes the vias or plated thru holes can be a problem and find it best to install small wire jumpers thru and solder on each side. I agree and never touch one that is working. My personal one has not been re-soldered or jumper wires installed and I have never had any intermittent display issues and I have not cleaned and re-torqued the ground plane to chassis. Now I am jinxed!

I have had pretty good luck troubleshooting the Counter Mixer board. It is actually pretty simple mixing scheme. Pretty easy to check the Mixers RF and LO inputs and the outputs. I always make sure have correct Carrier Osc, VCO, DC voltages, and bandswitch diode switching bias to the board first. Missing these or low in level it is pointless to signal trace or solder anything on the board.

I then go to Cin output and validate have all the band related frequencies at 1.0v rf. If any of these are missing almost always not getting the Low Pass Filters switched in and the bandswitch is the problem. Then go to Cin at Counter/Display input and if missing there you know Cin path is open between the two boards (bad solder). Now time to start re-soldering.

Now my track record with the Counter board is not as good as I do not understand the multiplexing aspect as well as I should. I built a few counters in the 70s that used the 7490/7475/7447 chips of that time, but havent worked on many counters over the years.

This fellow had adjusted several of the Counter Mixer board tuned circuits and needed to know what levels he is looking for to get them back to spec. Re-soldering wouldnt do that for him. That is what I gave him. He may end up having to do some re-soldering but to tell him to just heat everything he sees has an element of risk to it that wont undo what he has done. May end up there eventually, but not what I would recommend until he knows where he has lost his signal.

I am an odd bird. I like to understand how all the hybrid circuits work so I spend a lot of time studying and taking as found parameters on working units. Has paid off in spades for me having this data in my notes.

I understand you are looking at bench time so can see why you wouldnt want to spend too much time troubleshooting especially if your experience says resolder fixes 95% of all problems.

Terry K9TW

43903. Hi!

To be honest, I'm a Yaesu freak. I have about 15 of the beasts spreading across almost 40 years. Yesterday, the USPS delivered a Kenwood TS-820S from an eBay seller. It's my first Kenwood ever

It was a horrible out of box experience.

It wouldn't RX or TX, just got horrible splash. and the display wasn't functioning. I was bummed.

Let me take a moment to apologize to you ham guys out there. In a moment of adult insanity, I actually sat down and RTFM. Good thing. It was there I found out about the 9-pin external VFO sorting plug. I found it back in the shipping box, partially covered by some small-bubble bubble wrap. It had not survived the trip well and I spent about a half hour straightening pins before it would fit in.

OMG!! This radio is incredible. It's everything my Yaesu FT-901DM is (and a little more) and it cost me only about 2/3 as much. So I'm here to learn.

I have a ts530s that had trouble with the display not working on all bands. Also had drop outs on other bands. Cleaning the band switches on the RF board helped for awhile and was acting up again shortly. Traced it to the band switch itself. Moisture had taken it toll from storage of 10 years. Had to disassemble the RF board and the band switch segments and solder all the terminals of the switch as it seems that they had a high resistance on the circuit board. Reassembled everything and has been working great ever since. That was 5 years ago. This rig still has the S2001A finals that it came with 33 years ago and the output is about 85 - 90 watts depending on the band. I know, the book says 100 watts out. Big deal, 10 - 15 watts is not going to make a hill of beans on the other end. If you can hear them, you can work them. If the band conditions are right, you can work the world on 5 watts.

Rectifier tubes, excluding the Mercury Vapor Rectifier tubes, that are showing color on the plate(s) can also cause damage to the power transformer.

Bill:

Well not always band switch, but pretty common if missing Cin output at the Counter Mixer board.

I assume your TS530 is a Trio? Not sure when they transitioned to 6146Bs and do not know why. I believe the operating and service manuals of the time showed both S2001A and 6146B finals.

Without a little testing no way to know why output is down. My bet would be combination of things including rf drive being down assuming you are running originally 12BY7A. Easy to test that when you decide there is a need.

If finals cathode emission wasnt down a little on your 33 year old S2201A tubes then it would mean rig must have been used primarily as a receiver all those years. Have to assume yours has seen its share of filament on time. Clearly they dont owe you anything and you will be hard pressed to find any NOS replacements when you decide to return to as new.

Agree nothing to worry about at this time but hopefully you have thought about and procured replacements for when the time comes.

Not likely will get that kind of life out of finals available to us today unless the Chinese can get their act together.

I still see rigs come across the bench with S2001 and S2001A Matsushita Electric Industrial Co. finals from time to time that produce near spec output. Once had one that when I opened PA cage found that one of the S2001 envelopes got so hot it sucked the glass in. Obviously not a tube defect. (QRO mod)

Wish someone would make them again today to same quality standards that Matsushita apparently did.

> I have a ts530s that had trouble with the display not working on all bands. Also had drop outs on other bands. Cleaning the band switches on the RF board helped for awhile and was acting up again shortly. Traced it to the band switch itself. Moisture had taken it toll from storage of 10 years. Had to disassemble the RF board and the band switch segments and solder all the terminals of the switch as it seems that they had a high resistance on the circuit board. Reassembled everything and has been working great ever since. That was 5 years ago. This rig still has the S2001A finals that it came with 33 years ago and the output is about 85 - 90 watts depending on the band. I know, the book says 100 watts out. Big deal, 10 - 15 watts is not going to make a hill of beans on the other end. If you can hear them, you can work them. If the band conditions are right, you can work the world on 5 watts.

I have noticed a lot of chatter about building RF probes on here lately.
I recently found two EICO model "DP" probe kit's,unbuilt.
They are "direct" probe kit's, however the internal PCB has no foil on it, and could easily be adapted for use as an RF or any other style of probe you would like to build up.
One kit is complete in the package, the other is missing the instruction sheet, and ground wire/clip.
I would sell these cheap to members.
Contact me off site if interested.
Thank's.

Yes, it is a Kenwood TS530S. This rig has seen a few days of hard work as it has been to 7 field day events in the past. It went in to storage because of a mentally ill wife that I had to take care of until she passed. Two years ago I brought this out of storage as I didn't like the way my Ten Tec Jupiter preformed. The Kenwood has always been low in power since the day I bought it. One reason is ME.
I keep the plate current down around 200 ma. That is about 85-90 watts output. I had to repair the RF board as mentioned and it has worked fine until last week. We had some storms got through and we got a power surge here which blew out some light bulbs. The rig got some of it also. I had to replace the antenna relay as it was welded.
Got that fixed and found that I had a very bad hum on transmit audio, but receive was fine. I had to replace the screen caps on the IF board and I am still waiting for the power supply caps to come in. Should be here by Tuesday. I put it back on the air last night and everyone said it sounded fine. Not a whole lot of s-units, but the audio was clean. I did notice that the s-meter does respond as it did, so I will dig a little deeper. Maybe another bad cap. It don't take a lot to destroy 33 year old caps. These old caps were only expected to last 10 -15 years as it was. Love this rig and as long as I can find parts, I will keep it going. I may just order a complete recap kit for it and work it over good.

Very lucky didnt lose L41 ant transformer and Q1 RF amp. Sometimes after a surge like that you dont discover all that was hurt in the house for awhile.

Hard to come by original TR relay and pain to unsolder and replace.

Is your Marker signal same level as it was before lightning? Should be very close to S9 on 20 meters.

Might want to look at 9vdc and RF-1 to make sure they are still to spec.

I hate to disagree Jim but in my case I spent WAY too much time resolidering everything only to find out that 5 minutes of troubleshooting could have saved me some frustration since my problem turned out to be an open choke in the DG-1. If you haven't already, see 2nd post of this thread.

I realize I'm just splitting hairs...but it apparently isn't ALWAYS poor soldiering. :)

43912. Screen Grid Protection MOV specs

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-10 14:56:09 UTC
From: Terry Wagoner
Topic: 43912 Message: 43912

I have had several requests off list to explain how I selected the MOV to provide screen grid protection. I thought I had provided this previously but cant find the message number or anything in the files so here it is. Again must emphasize I have not had anyone with formal EE education validate my methodology.

From experience I can tell you it wont hurt your rig, but cannot guarantee it will provide the protection it is intended for.

Objectives:
1. Limit SG voltage to approx 300vdc in event of tube arc over.
2. Have no MOV clamping action at screen grid voltages encountered in receive mode:

How sized:
1. Measure Screen Grid dc voltage in receive mode.
2. Multiply that value by 10% to allow for 120vac line voltage variations.
3. Add result from 2 to 1.
4. From Littlefuse or other MOV catalogs select Vnom value. This is the dc voltage where the MOV transitions to clamping resistance value under high current. In this case I selected 20vdc
5. Add Vnom (20vdc) to Step 3 results
6. From Littlefuse or other MOV catalog select a MOV that is close to the total VDC arrived at in Step 5.

Note: You will have a choice of Joule ratings. I made no attempt to estimate the joules of energy for assumed fault current. I picked a physical size that was practical and did not consider paralleling MOVs.

My calcs based on measuring Screen Grid voltage on 2 TS-830S radios:
1. 265vdc
2. 265 x 10% = 26.5vdc
3. 265vdc + 26.5vdc = 291.5vdc
4. 20vdc = Vnom
5. 291.5vdc + 20vdc = 311.5vdc

Select a MOV that has approx 310vdc rating.

With this value of MOV connected from Screen Grid to chassis ground there should be no dc current flow with maximum screen grid voltage levels at maximum line voltage variation in receive mode.

Lastly, it is imperative that you have the proper size fuse protecting your radio. If you have never checked it suggest you do that and make sure no one has substituted higher amperage or automotive type fuse.

Remember the 520s and 820 use a 3AG 4 amp and the 530/830 use a 3AG 6 amp due to higher dc input power rating.

Hi Terry,

"Remember the 520s and 820 use a 3AG 4 amp and the 530/830 use a 3AG 6 amp due to higher dc input power rating."

My 820 op manual indicates '120V 6A, 220V 4A fuses @ 160W input power CW'.
What's the 830 input power on CW?

Thanks

Dave: Good Catch! So much for priding myself on attention to detail.

You are correct I looked at page 14 Item 9 where it states 3AG 4Amp. I failed to read top of next paragraph. Also, all the Hybrids have labels on the rear panels at the fuse holder that shows fuse amperage rating. I should have remembered that as well.

But hopefully my error wont spoil the message. Make sure you have the correct fuse amperage and fuse type installed.

The point I was trying to make is the glitch resistor, meter diode string, MOV wont do any good if you have placed a "penny in the fuse box." Have to have lived in the 50s with two fuses and 30amp service to the house!

Idea is for these protective devices to shunt the voltage to ground and be able to withstand the current flow to allow fuse time to act and clear the fault. Fuse should be sacrificial element and not radio components. Installing bigger fuses or fuses with different fault clearing characteristics could negate the protection devices action.

The TS530 and TS830 are rated at 180watts dc input CW mode. That is why CW mode Ip level is higher for them.

The TS820S primary wattage is approx max of 292 watts in TX mode. 292/120 = 2.43 amps. I supposes they use a 6 amp primary fuse to allow for initial current surge during power on?

The TS830S primary wattage is approx max of 295 watts in TX mode. 295/120 = 2.46 amps.

I have never placed a clamp-on ammeter on the line cord when key down into dummy load at 100 watts. Might try that one of these days.

So if you look at ac wattage the TS820S and TS830S ratings are very close.

Interesting that one is rated 160 watts dc input and the other 180 watts dc input. I have to think primary limiting factor was the final tube dissipation ratings, but as I have mentioned here before I have never seen a Matsushita S2001A data sheet.

I think 6146B were originally installed in the TS-820S, but dont know that for certain. Have seen them come across bench with S2001A installed. If both tubes were issued with 6146B then I have no idea why they have different CW dc input power ratings. Perhaps the VA rating of the power transformer was slightly less for the TS-820???

Again glad to see someone is reading and thanks for the catch. I appreciate that.

Terry,
Your focus is solid as ever.

The fuse rating also depends on the mains AC rms voltage applied to the rig.
For TS-820S 220U operation, 292W / 220U = 1.33A.(4 A fuse.)

My 820 transformer is part no.L01-1056-05 from the Service Manual.
Is the 830 use the same part no. / interchangeable?

My 820 has original S2001As and my Op.Manual specifies the same.

Thanks Terry for your interesting info on rig protection.

To All,
A quick heads-up on DeOxit.
Lots of previous posts call for evaporation of the solvent carrier befor energising.
I just 'repaired' a house fan and used DeOxit to free a sticky sintered bearing.
Switched on too early and BANG! Nice explosion and carbon film deposits.
The warnings are real!
This is not a new thread. No responses required.

Cheers
Dave f4eyk

Dave,

Dave, I hope you, your family, and your house/home were not injured in the explosion. I'm also glad you posted your experience, albeit a bad experience, using DeoXit D5 contact cleaner. We can all learn from this, pay attention, take the time to read the warning labels on the cleaner cans, don't be in a hurry, and adhere to those warnings! As Dave said, the warning labels are there for a purpose!

Road the tractor and mowed the ranch. Thought about the approx 295 watts @ 120vac draw in Hybrid TX mode as I mowed. Lines not so straight now! 295 watts consumed to make 100 watts?

If I am paying my utility for 300 watts why am I only getting out 100 watts?

I dont think very many of us ever give any thought to what the ac line current to our rigs is or what wattage is being consumed. Hard to remember that these grey boxes are really just energy conversion devices that take 120vac at 50/60 hz from the wall receptacle and converts it to 71rf volts at 14.2 mhz. I guess last time I thought about it was when I needed that 220vac line run to shack for that "Full Gallon" converter device.

Very seldom think about that our Hybrids present approx 300 watt load to our KWH meter on the house. Lets see 100 watts out at 14.2mhz divided by 300 watts in at 60hz = 33.34% efficiency. So the overall conversion cycle efficiency isnt all that good or is it?

We all talk in terms of the PA efficiency in Class AB1 config at approx 55% efficiency. We are talking about the tube converting the HV DC power supply 800vdc at 200ma to RF and not the entire conversion process. 800vdc X 200ma = 160 watts DC input. Where is the rest being consumed or lost at?

Well lots of places come to mind. Pilot lamps, fan motor, power transformer hysteresis, eddy currents, and copper losses, 14 vdc choke losses from same reasons as the transformer, Pi-network losses (probably 3% to 6% depending on the band), 9vdc and 12vdc linear series pass regulator transistors etc. All being lost as heat.

All energy conversion schemes have losses. What about what is on the other end of that 120vac receptacle on the wall. Utility uses Coal, Oil, Natural Gas, and Nuclear fuels in their power plants for energy conversion. They use these fuels as sources of heat to boil water to make steam to turn a turbine to turn a generator. If we think of Coal which is where bulk of our 120vac comes from here is the efficiency cycle.

The maximum theoretical efficiency of a coal fired plant is 61% (Rankine cycle). Energy leaving the plant divided by Coal consumed by the plant = 61%. Actual efficiency is considerably less averaging approx 34%. We have seen that number before. Most is lost as rejected heat from the Steam Turbine Condenser to the river, lake, ocean, or cooling tower. Auxiliary systems like precipitators and scrubbers consume a lot of power.

Coal plants talk in terms of Heat Rate. Average heat rate for coal plants is approx 10,400BTU/KWH and very best plants are around 8,500BTU/KWH. A ton of coal(2000lbs) has approx 20 million BTUs. One pound lump of coal has approx 10,000 BTUs and can produce approx 1KWH of electricity. The utility also sees losses after the energy leaves the plant. These are primarily due to step up and step down transformer losses and the losses in the miles and miles of transmission lines and distribution network. I dont know what the total cycle loss is from lump of coal to your KWH meter on the house is.

So we take this black lump of carbon out of the ground and burn it and convert it to 120vac at 60hz for our Kenwood Hybrids which in turn converts the 120VAC to 71rf volts at 14.2mhz.

We buy 295 watts from the utility to produce 100 watts. Doesnt sound to bad if we say that we can run the rig in TX mode key down for 3 hours on a 1 pound lump of coal. Gives a whole different meaning to placing a brick on the key!

Fun to think about that black lump of coal in one hand and 100 watts of RF out the SO-239 connector in the other. Now think about the gallon of fuel oil or that cu ft of natural gas or those enriched uranium pellets in a fuel rod. I remember when Nuclear power came on line in the 70s and heard that it was going to be too cheap to meter! I dont think that has exactly worked out. Sure seems like a lot of trouble for 34% efficiency, but a lot of fun for us.

Sorry for the tangent. Nearly 40 years in utility business hard to get out of your system.

Dave:

The TS-520S and TS-820S have the same power transformer by part number. The TS-530 and TS-830 have different part number L01-8105-15.

I assume that the VA rating for the TS530/TS830 is higher. I have no idea about core dimensions or weight. I believe that the bolt centers are different so the TS530/TS830S transformer will not interchange with the TS520S/TS820S.

Bob Mansker could tell you for certain.

Rough rules of thumb for estimating E/I lamination transformer VA rating includes using 10 watts/pound and (5.58 X Core Area)^2 = VA.

There is a voltage droop test using dummy load power resistors you can also perform that will allow you to estimate the transformer VA. I have never performed it.

I have never compared Core area dimensions or weighed either transformer.

Any time I needed a replacement transformer I would contact Bob Mansker to get an exact replacement and that should not be very often.

Did it previously get more output on 10 meters while you owned and operated it?

Try new 12BY7A Driver Tube first and then do a good Coil Pack alignment for starters.

Ken:

Just be sure you don't do what I have done - and more than once:

I.E., Tune up on 10M and marvel that the power out is so much lower - but without trying to turn up the carrier level on CW or mike level on SSB.

It is normal to have to turn up the mike or carrier levels on 10M, even though you may not have to touch them on all the lower bands.

I have sworn on here that I only got 20W on 10M - and then had a thought, went back to the rig, turned up the carrier or mike gain and got 100W.

Good luck!

I just got a Kenwood TS-520S and and figuring out how to work it. I have got the tuning down, I am using K4EAA procudures. The problem is that some times I will transmit on SSB and some time it will not. I will transmit on CW alway but not on SSB. The meter on the 520 does show some movement but the extenal meter I have show nothing. I can hear the relay in side clicking.

Todd,

I have seen that be one of the high voltage supply capacitors that has
given up the ghost. Let one of the "guru's" check in though, as there
are likely other causes. In either case, be VERY working around the
high voltage supply if you have not done so before. Discharge the
capacitors and observe proper high voltage precautions.

43928. Calibrating AT-230

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-11 04:10:45 UTC
From: Craig Roberts
Topic: 43926 Message: 43928

I have just acquired a very nice AT-230 antenna tuner. As a tuner it works great. As a wattmeter, however, it's not so good. At the 100 watt level (225 mA / dummy load) it reads about 15 watts below my lab calibrated Bird 43 and Drake W-4. This hurts nothing really, but it'd be nice to have the Kenwood reading properly, too.

So, does anyone know the calibration routine for the AT230's bridge? It looks as if you'd null VR1 then adjust VR2 (100W) and VR3 (20W) for proper readings against a known measurement (like my other wattmeters).

Anybody done this?

Thanks and 73,

Craig

Craig:

I have never seen a service manual for an AT-230. Question comes to mind how would directional coupler get out of cal unless someone had tweaked the trim pots? Hopefully no one attempted to put more than 200 watts thru it.

I think I would take a look at L1 and L2 windings to see if any signs of discoloration or overheating. I would also measure R1 and R2.

If this looks good I would try this:
1. On 14.200 mhz load to 100 watts into 50 ohm dummy load.
2. Place in SWR Forward and adjust Cal control for full scale deflection (cal position). (Just as manual tells you to do)
3. Flip to Reflected power and adjust VR-1 trim pot for zero on the meter (or whatever reflected your Bird is indicating)
4. Now switch to 200 watts and adjust VR-2 for 100 watts indicated (match what your Bird is showing)
5. Now reduce CAR Level pot for 20 watts indicated on the Bird meter.
6. Now switch AT-230 to 20 watts range and adjust VR-3 for 20 watts indicated (match what your Bird is showing).
7. Repeat until AT-230 matches your Bird.

Would be nice to have several other dummy load values to check VSWR. If you have couple of 50 ohm dummy loads can place in parallel or series to get a 2:1 test load.

This is educated guess and not from AT-230 experience. Only follow if no one else can provide you with the Kenwood alignment procedure.

Jim:

No you dont need matched finals.

No disrespect but the tubes will have nothing to do with having zero output in SSB mode if you have good output in CW mode.

Have you tried running mic gain full CW?

Is VOX turned off?

Do you get any ALC indication (meter switch in ALC position) when you speak into the mic?

Does it have zero output in both LSB and USB?

But just in case you go ahead and swap them anyway (KEEP the original ones, they're very likely still good and you can use them as spares when you get the thing running.) against Terry's advice, they DO need to be neutralized.

If you will dig into the archives of this list, you might notice the name "Terry Wagoner" popping up A LOT on posts, with really REALLY good step-by-step instructions on how to troubleshoot Kenwood Hybrid gear (and to learn to troubleshoot about any electronic device if you apply the principles on your own), followed shortly by a reply, "It works now, thanks!"

And several others here. They're better than good, they are a great resource for these rigs. If you will carefully follow Terry's directions, sending the information back which he asks for AND KEEPING GOOD NOTES for yourself, you will quite probably get a working rig out of the bargain.

Not being snide or rude or disrespectful here, but you've been offered help that you couldn't possibly pay for, be you as rich as Croesus, and an education in hybrid ham gear troubleshooting in the bargain.

REALLY recommend you give his way a try, and see what happens. Nobody wins 'em all, but Terry and this crew have a lot higher batting average than anyone in the majors. And they don't charge for it.

(I'm picking on Terry here particularly, only because - of all the knowledgeable people who help folks repair their rigs on this mailing list - he jumped in first. He isn't the only wizard in here.)

Craig,
Good afternoon. I have no experience with the AT-230 but I do have a service manual and schematic. I think you should have a copy if you are going to put this piece into service. Terry is pretty well on the mark with the adjustments and I have used that method on various tuner meters over the years so you would be safe doing it that way. It is not much different than the manual instructions and pretty straight forward. I can attempt to scan what I have and put it in the files section if you desire. The manual is only 2 pages and includes the schematic so you know it is not overflowing with info. Let me know if you would like to see it in the files section and I will put it there. If anyone else would like to see it and Craig does not respond, let me know.
73 and enjoy,
Don K5HFG

James. Not sure if you have been asked this before, and no insult is intended. Do you have a manual,and if so, have you thoroughly read it? Do you have or have access to the proper test equipment? Are you experienced working with LETHAL levels of high voltage?
So, as a first step, ask yourself all of those questions, and then let the group know your answers so that they will know how to help you.

One common theme expressed here constantly by Terry and the other experienced guys is that these are OLD and somewhat fragile radios...so you can do more damage sometimes by the simple act of replacing a tube, using a modern DMM instead of a true VTVM, and, THE WRONG VERSION OF THE MANUAL...it appears that there have been many many typos, bad diagrams, etc.
Hope this helps,

Bob/WA2JAJ

Terry is retired with health issues so sitting long hours at computer trying to help folks is way he gives back and exercises his brain and hopefully will stave off "old timers" disease!

Not a wizard just have the interest, the aptitude and been doing this a long time and certainly fallible.

Must admit that having to play "twenty questions" does get a little old at times.

Other options include making video series, compiling notes into a operating and maintenance manual,or posting white papers, procedures, and FAQs on a website. Lots of work to do both.

Real goal is to try to develop new folks to hold up the tent poles when old timers are gone. I guess fellows like me and Mike W5RKL qualify as we came up in the hobby many years ago in a very different manner.

Maybe Gordon can post the Service Manual on his website as well?

Terry is pretty well on the mark with the adjustments and I have used that method on various tuner meters over the years so you would be safe doing it that way. It is not much different than the manual instructions and pretty straight forward. I can attempt to scan what I have and put it in the files section if you desire. The manual is only 2 pages and includes the schematic so you know it is not overflowing with info. Let me know if you would like to see it in the files section and I will put it there. If anyone else would like to see it and Craig does not respond, let me know.

If nobody else pops up, I'd love to see it in some archive or other. I see these come up for sale once in awhile and have wondered if getting one (close match for the 520 and other hybrids in looks, on purpose I'd suspect) might not be a bad idea.

The more manuals available, the better, say I. So if it wouldn't be too much trouble, please? Scan it in at the best resolution you can get, and thank you for doing it.

Bob:

Good counsel. That old Burns adage about "the gift he gave us to see ourselves as others see us" comes to mind.

This forum is a great resource, but 90% of folks who post provide no biographical info so all we can do is form an opinion based on our initial impressions from the read.

Command of the language comes in to play. Grammar, sentence structure, use of correct terminology and technical parlance gives us a clue. In fairness we simply do not know anything about the poster.

It usually takes two or three exchanges and we can pretty much tell about knowledge and experience level.

Regards the Fatal voltages Mike W5RKL and I have discussed our concerns about this and have considered posting a disclaimer regards using any advice provided on the forum.

Having to be wary of hurting feelings is not my strong suit. I would rather hurt feelings than see some one physically hurt or worse.

You also make a good point about these old radios. I never recommend to anyone as a routine step to remove and clean boards or unplug and clean and re-plug every molex connector etc. Very easy to induce new faults in these old radios. Some new faults will be evident if you break something or pull a molex connector off a board and others will be latent (wont show up until some time later perhaps as an intermittent). For example it is easy to crack a trace rocking molex connectors back and forth.

So giving a short bio that includes telling what documentation you have and what test equipment you have available in your initial post would be a big help and appreciated.

Hi Terry,

I just checked Gordon's site and the operating manual is there. After you inquired I thought I had seen it and went to check. So, I am saved the embarrassment of trying my hand at computer aided graphic arts. Any how, What you told Craig I have done on quite a few old tuners and It works fine. Some of these things get a bit off from sitting for years in non climate controlled atmospheres but most I have reworked were tampered with at some time in there life. I adjust everything to my Bird 43 with proper slug inserted and at least I am looking at the same reading all around. Unless the meter is non responsive to begin with it never amounts to that much difference in my experience. I will have to go back and re-read Craigs post. I can not remember his exact problem.

Everyone should check there TS 530 service manual if they have original KW document. Mine is from 1983 and it includes the VFO 240 and AT 230.

There is no actual Kenwood AT-230 service manual. I created it from the AT-230 service information that is in the TS-830 manual. This was in response several years ago from some of my customers who picked up AT-230's at flea markets and didn't want to spend the money for the entire TS830 service manual.

43943. KENWOOD HYBRID USER NET (August 11th, update)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-11 19:14:05 UTC
From: mvgilger
Topic: 43943 Message: 43943

The Saturday's net on 40 meter was run by Jimmy, WB2KNR. He had 21 stations checking in under good band conditions. We had 6 new check-in, WA2RVJ, WA1RWN, W4SOH, and K1TSW. Out of those, there was:

4 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
4 running TS-830S
1 running TS-900

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 11 stations checking in under good band conditions. We had 3 new check-in KD0JQF, N0KAB, and KD0TWV Out of those, there was:

3 running TS-520(x)
0 running TS-530(x)
2 running TS-820(x)
4 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39

April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 45, Sunday's total = 50
June 2013, Saturday's net total = 30, Sunday's total = 27
July 2013, Saturday's net total = 63, Sunday's total = 41
August 2013, Saturday's net total = 40, Sunday's total = 27 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Thanks Pete,
I uploaded a file with the adjustment info on it from the TS-530 Service Manual. The File service is at max so it would not let me load
any more files. This along with what is on Gordon's web site should give you the info you need, Craig.

Don:

I knew that Gordon had the Operating manual which just tells you hands off on the wattmeter cal trimmers.

I forgot that the TS-530 Service Manual has the AT-230 in it. I also did not think about swapping the dummy load and input cable connections to do the reverse trimmer adjust.

Some wattmeters with reflected power positions have you disconnect the output coax from the dummy load and make the adjustment with the transmitter output opened ended. That makes you nervous and need to make sure have transmitter tank tuned to resonance. First time I encountered that one I had to think about it for awhile before I got brave enough to try it. Operating your transmitter without a load is something would not want to do for very long time.

Terry,
Yep, I never do that. Don't trust myself to remember where I am. But,like I said ,Unless the unit has been badly mistreated I never find much adjustment needed. but I like to have every thing I use in my shack calibrated to my known Bird. I even hook them up in tandem with my tuners now and then just to check.(talk about anal!)I could only load the one PDF file into the files section because space was all used up. I think I will send the files to Gordon if he wants to put them in with existing files. I will let him decide.

No need to load anything as we all have access to AT-230, TS-530 and TS-830 manuals on Gordon N6WK, Ron WB4HFN, and Dick W0NTA websites. I thought you had a Kenwood produced and published AT-230 Service Manual which I had never seen before and that piqued my interest.

Pete cleared that up for us by confirming that none exists.

Thanks
Terry

Yes that did not help
>
> Is VOX turned off
Yes
>
> Do you get any ALC indication (meter switch in ALC position) when you speak into the mic
No When I key the mic them meter goes to zero
>
> Does it have zero output in both LSB and USB?
Yes

I tried to clean the relay but that did not help

tuning down, I am using K4EAA procudures. The problem is that some times I will transmit on SSB and some time it will not. I will transmit on CW alway but not on SSB. The meter on the 520 does show some movement but the extenal meter I have show nothing. I can hear the relay in side clicking.

Topic: 43925 Message: 43953

Jim:

Are you saying sometimes you do have rf output in SSB mode displayed on your external wattmeter for a long enough time period that you could make a contact?

So when it is working in SSB and you have coax jumper from rig connected to a dummy load is this what you see:
1. Meter in ALC position
2. Mic Gain at 1200
3. Mode switch either LSB or USB
4. Push the mic PTT and speak into the mic. The meter indicator swings within the black rectangular ALC box printed on the meter face.
5. Your external wattmeter reads approx 25 to 30 watts maximum on voice peaks.

Is this correct?

It would be very good if you have a local club close to you that you could ask if there is an experienced Kenwood or boatanchor transmitter person who could help you. No shame in that at all. Always helps when someone can explain and demonstrate.

Lastly when you said you cleaned the relay do you mean you cleaned both relays and/or swapped them? How did you clean them?

This is beginning to sound like missing ALC bus voltage via the AGL line which is switched by your aux relay. No ALC bus voltage means no TIF amp signal from the IF board. This may not mean much to you now but if you look at block diagram for transmit and read circuit description can see how SSB signal is produced.

Common cause of intermittent operation is AuX relay contacts. Cleaning may not fix it.

Thanks to all. I have downloaded the AT-230 user manual and had forgotten that a section of the 530S manual contains info on the tuner (and external VFO).

At any rate, shortly after I posted my message last night I just went ahead and tweaked the tuner. Piece 'o cake -- just touched up the "do not disturb" trimmers with my dummy load and Bird 43 as a reference. The AT-230 now matches the Bird on all bands, forward and reflected.

The tuner shows no signs of unpleasantness, but a previous owner apparently invaded it at some point as evidenced by the bunged up case screws. Why? Who knows.

Thanks again,

Craig

Lots of the abbreviation's i know and lots i don't know regarding the connector pins layout on the schematic.
Maybe if you get time you could compile a list of them.
Example,Alc is a easy one,but ones like,mo,me,ss [short stop hi hi] ste,av1.nbi, just to name a few would be nice to know
Glossary definitions for those terms would be handy to reference to

Don,

  G'day. I have found it helpful to look at fold-out page 62 of the TS-830S service manual. It lists specific connector numbers and terminals which are specific to the 830...but I have found that the descriptions(abbreviations) seems to be standard usage by Kenwood

   cheers

Don:

I have never seen a list published. Your service manual has a page of Schematic Abbreviations that generally describes the terminals but not necessarily the exact definitions that Kenwood had in mind.

If you study this list and the schematic can pretty well figure them out. Some folks may translate them slightly different. For example SS is most likely Stand-by Switch, but nothing wrong with calling it Send Switch.

More important that you understand the abbreviation function.

STE would be Side Tone Enable but I once saw a fellow call is Side Tone Emitter because it grounds the emitters.

MO = Marker Output or Monitor Output (depends on what board/connector)

AV1 = Audio Volume 1 which is the top terminal of the Audio Volume pot but OK to call it Audio Gain pot.

AV2 = The wiper of the Audio Gain pot. I guess translation would be Audio Volume 2.

If you get stuck on any really cryptic ones ask here and someone should be able to help.

Do you think it is not running because you cannot hear it or because you have looked and it is not spinning?

By design the fan is run on reduced voltage so if bushings are free and lubed it runs whisper quiet.

Topic: 43958 Message: 43963

After installing accessory CW filters in my TS-830S, I decided to finish my extensive refurbishing of this fine and fully operational radio with a final cleaning of cracks, crevices, nooks and crannies with the aid of my nifty air compressor. I did this outdoors and, in full sunlight, observed a disturbing sight. Tiny but numerous rivulets of liquid emerged from secret hiding places on my RF Board. Now, I had cleaned the bandswitch contacts with DeoxIT as a first step in the "get it going" stage of the radio's service (it was pretty much dead as delivered). However, I had applied the cleaner sparingly using a tiny brush and a syringe on the individual contacts. I had done no wholesale spraying of the red stuff. Apparently, however, a previous proprietor had showered the board with a contact cleaner of some sort (given its color, seemingly not DeoxIT).

I would like to flush this stuff off the board along with the congealed dust slurry it's formed. I was able to remove some of the mess with compressed air and Q-Tips, but much remains tucked away amongst the densely packed board components. Is there ANY way using ANY agent that would allow me to safely flush the top side of the RF Board while it is in place? Yes, I know I could remove it, soak in in a mild detergent solution, blow dry it and let it sit in the sun for 7 months, but -- honestly -- I hate to disturb something that's working by removing and replacing if there's a safe and efficient alternative.

Has anyone performed such an operation?

Thanks again,

Craig

Terry:

We have discussed here the need to rewrite the TS-820 Operating Manual and the Service manual, but each time that ends up sounding suspicioulsy like a lot of work. And as someone who is at least theoretically a professional writer (who would theoretically starve) I can confirm that impression.

Maybe a still useful but much easier task would be to publish a new set of "service bulletins." Take those old Kenwood Service Bulletins, vet and clarify those that that are verified or at least seem reasonable, and add some new ones.

Then direct newcomers asking questions to first look those service bulletins up in the group files and and run through them, even before studying the manual. When I started working on my first TS-520 and my TS-820S I studied the Service Bulletins and implemented some fixes based on them - some of which were not needed. But it was easier to first look at the Service Bulletins than to plough through those confusing manuals, which I got to eventually.

Best Regards,

Robert

Very easy to pull off of back panel & clean (be sure power is off)..
The bushings have a small hole for oil, also a felt material inside to hold the oil...
I use Amsoil Synthetic & a small injection needle to oil...
Fan should spin freely when spun with your finger...
DON'T stick your finger into the fan hole as it takes a little time for the bleeder resisters to bleed off the voltage on the finals...

Terry

If you recall i mentioned i was getting a unseen parts radio to use for parts on that Ebay special we were working on[Ebay special on hold for now and more on that later]
I have gotten the parts in from a Ebay seller for the Ebay special as the Hybrid store did not answer my email regarding parts.[think he was doing maintenance on his site?]
I got the parts radio last week and to my surprise it was in real nice condition inside and out.I got the radio for the price of a set of tubes.
The owner had told me it did not transmit very well and he had replaced the coupler,and did the coil adjustments.
He even sent a small box of parts he got from Ken,RK-53 and FR-100 not installed plus a driver tube.
This radio was too nice to become a parts radio,so i fired it up and only found that 40 meters was not working,on transmit and very poor rec.
I removed the driver tube and reinstalled another one and bingo i had a good signal on 40 meters.
When i went to load the rig and hit the send switch the signal would disappear.
I would reinstall the driver tube and i had the signal back,as every time i hit the send switch the signal would disappear on the band i was trying to load,not just 40 meters.
So i am thinking maybe bad solder joints on the driver socket,or a relay problem
I did not realize that the lower and upper side bands relay would not work with the vox gain turned off as i could not hear them click in,so they were fine after i turned it on.
Good way to save wear and tear on the relay if you listen more than operate.
I decided to redo the coils packs[5 times] and they were out of adjustment and to my surprise all bands were working,except ten meters,good rec but little output.
As you say it's nice to have a good working rig to compare to another one.
The maker signal gives me about S7 To S8 compared to my good one that read S9 or better.
The only way i can get output on ten meter[about 40 watts] is to load it in RF meter position only as i have no Alc and little ip reading.
I can peak the rec coils,but not the driver coil as no reading.
Seems to be a common problem as per other posts you have made regarding ten meters
Would the kit Ken sells help,HV-22 as when i test the bus line it drops from 335 Vdc to 282 Vdc with a load on them

Craig:

Well, first, DO NOT USE CRC Electro Motive cleaner for this purpose. It's impressive stuff, but is designed for motors and such. On WWII vintage equipment, it's probably fine; at least, I had no problem with it on BC-348's. On anything later than about 1960 its a death sentence for the radio.

And I would not use WD-40, either. Although it might dissolve the goop, and is designed as a cleaner, it was meant for keeping Atlas missile skins corrosion free, not for electronics.

I'd use CRC QD Electronic Cleaner, or the marine version of it. Some ACE hardware stores and possibly even Wal Mart sells it.

Good luck!

Robert

Subject: Re: [TS-520_820_530_830] Abbreviations

HI Joe

Your right Joe,as i did not read the back pages,mainly due to i use the
pdf file schematic all the time
as i can blow them up to more easily read it as the eye's are not the
greatest anymore.
Guess i should take more time to read the manual front to back,so i
don't have egg on my face hi hi
I also could not survive with out a mag light to troubleshoot my rigs.
I can see a airplane 30,000 ft in the air,but i cannot read small
print,without glasses and my mag lamp

Robert:

What you suggest is certainly something that is needed in addition to service manual rewrite. Agree a one page bulletin much easier to digest than a service manual.

I always tell new folks to gather all the documentation they can find for their rig and that includes whatever is being presented as a factory service bulletin, mods etc. However I always caution them not to rush off and start performing any of them without coming to this forum and asking especially after reviewing it just doesnt make good sense.

I just hate it when I see things like "If Receiver gain is down or Receiver is dead replace Q1 mosfet on RF board". You will see one line entry after one line entry giving a list of components to replace to correct no receive condition. This isnt troubleshooting. Might be what you get at auto dealership today just put on new parts until it is fixed. No one in right mind would do that with their hybrid. The existing service bulletins abound with that kind of advice.

I wish some of us lived closer and we could form a working group and rewrite the 820 service manual and the service bulletins.

I guess with computer we dont have to be in same room or local.

I wanted to see a service manual that each step started out with very brief description of what the step was intended to accomplish. Then list the required test equipment or alternate means if that gear wasnt available. Then list pre-conditions such as the control settings. Then list the test points, the adjustment points, and the acceptance criteria. Maybe list results in terms of dBm,dBu, Uv etc. Then list any Cautions personal safety or otherwise just before performing a step.Then the performance steps sequence. Then maybe what to do if you dont get expected results.

Probably too much detail. I think that all service manuals start with premise that the tech using them has a certain reading level and a certain knowledge and experience level. Cant teach them how to use a Rf sig gen and step attenuator

Maybe use the matrix format like the TS-530/830 but expand upon it. A good tech writer would be big help once format was established and then couple of experienced TS-820 techs to serve as Subject Matter Experts.

I think agreeing on a format would be first big hurdle.

Maybe you and I could work together to produce a "straw man" to present for critque? Maybe start on page one of the service manual and rewrite it in the TS-830 format? I could provide any corrections that I have in my notes.

Or as you say pick a Service Bulletin (No 21?) and rewrite it?

I am not a procedure writer and not very computer literate. Would serve better as an SME. I have been spoiled by Nuke power plant play script style procedures.

>
> Maybe a still useful but much easier task would be to publish a new set of "service bulletins." Take those old Kenwood Service Bulletins, vet and clarify those that that are verified or at least seem reasonable, and add some new ones.
>
> Then direct newcomers asking questions to first look those service bulletins up in the group files and and run through them, even before studying the manual. When I started working on my first TS-520 and my TS-820S I studied the Service Bulletins and implemented some fixes based on them - some of which were not needed. But it was easier to first look at the Service Bulletins than to plough through those confusing manuals, which I got to eventually.

Okay. I finally just gotta ask:

HOW DO YOU ---DO--- THAT????

I keep hearing how so-and-so has nineteen rigs in pristine condition
that they never even use; such-and-such other person got a really sweet
rig for peanuts; or who's-it was given a new-in-the-box gadget by a
little old lady they met on the street; or old-what's-his-name found a
perfect dingus worth a small fortune, in a box at a garage sale for a
dollar, and so on.

HOW DO YOU MANAGE TO DO THAT? AND CAN YOU TEACH ME?????

I look, I browse, I dig around in piles of schmutter looking for usable
bits. I schmooze with other hams, I haunt junk shops, and all I ever
find are pieces, bits, and much-too-broken half-burned JUNK.... For
BRAND-NEW money (which they don't get because I don't HAVE that sort of
expendable cash, and know better than to buy garbage anyway).

I spent <mumble-mumble-too-many!> clams on this 520SE, supposedly in
perfect condition, from what I thought was a reputable local ham, and it
has YET to even power up.

(Eventually, maybe. Had to stop with the radio for a bit, I'm now
working on the V7A Heathkit VTVM, so I can work on my O-scope and signal
genny, so I can work on the 520.... Making the tool to make the tool to
make the tool to fix the other thing is starting to really get me down.
Oh, and my old grid dipper is now hors de combat, too. All the magic
smoke came out last week. It's probably not worth trying to resurrect,
considering the cost and that there are now other, better, options.)

I wish I knew how y'all do it. I truly do.

Sorry, probably sounds like sour grapes. It's truly not.

It's sheer admiration, with a small touch of envy, admittedly.

It has to be some sort of skill, or something, or it wouldn't keep
happening to the same people all the time. (The "nineteen rigs" number
was NOT picked out of the air.)

Me hat's off to you. Hope the new "parts rig" keeps working for another
thirty years for you after you tighten the one solder joint or whatever
is actually wrong with it.

It's all skill hi hi
I have learned one thing in life is that never rush to buy or overpay
for something as there is always another one
Had a fellow send me a Heathkit HW9 just for the shipping cost as he
could not get it going and all it was,was a diode
Think he paid $150 for it.Told him i fixed it and would he want it back
and he said no.
Just had a ham sell me all his test equipment for a $100,well worth 2k
as he got remarried and sold all his ham stuff.He will be sorry.
Hate to tell you what i paid for a mint TS 830 and matching vfo both
with KB-1deluxe vfo knobs.

If i break even in life i figure i have done well

Now, now, Will. It's not skill or even luck that presents certain individuals with widow--down-the-street gifts of late husbands' new-in-the-crate-still-smeared-with-Cosmoline Collins KWS-1s with spare finals. ("I hear you like to tinker with old radios, so you can have Ralph's old thingamabob if you can get it out of the basement...")

It's karma, Will. You -- and I -- were apparently very, very bad people in previous lives.

Best deal I ever made was a fellow emailed me several years ago and said
he had a non-working TS-830 to sell me.
Asked if I would pay $175.00 for it with shipping. I said YES!
When it arrived, included was a MC-60 Mic, VFO-230, AT-230 and the
TS-830S. I could NOT believe it!
When I opened up the 830, I found it had ALL the filters installed and
was in pristine condition.
It took very little to get the 830 going and served me well for many years.
Like I said, it was a once in a lifetime deal!

The best I've found for this application is Techspray Precision V
Plastic-Safe Universal Cleaner. Not inexpensive, but an excellent
commercial cleaner. Techspray's Blue Shower cleaner is also very good,
but not totally 100% safe for all plastics.

I did exactly what you are considering on one of my hybrids, and it came
out perfect with no residue remaining.

Hi Gordon. Nice.
   Have you made parole yet? (hi)
   I once stumbled on a gent opening his car trunk to set up at the fleas. I saw a Collins 32V-2 and Hammarlund HQ-180A in clearly Excellent shape. Helped him unload, and when he quoted me $80 and $50, I (feeling some guilt) asked, "are you sure"? He told me he had a list in the car, so I waited. Producing the list, he said yes, there they are." I did the deal and have cared for and used them, as found, for 15 years.
   Last year I heard a report about a new TS-520S in my neighborhood.
She said it was bought new for the ex, who used it once, to listen for 10 minutes. He never got his ticket, and it had been sitting, covered at her place ever since. Gladly paid the $225. Worked 100% and still does. Only needed VFO exercised. Appears to be Mint.

Best deal I ever made was a fellow emailed me several years ago and said
he had a non-working TS-830 to sell me.
Asked if I would pay $175.00 for it with shipping. I said YES!
When it arrived, included was a MC-60 Mic, VFO-230, AT-230 and the
TS-830S. I could NOT believe it!
When I opened up the 830, I found it had ALL the filters installed and
was in pristine condition.
It took very little to get the 830 going and served me well for many years.
Like I said, it was a once in a lifetime deal!

73,
Gordon

Nice to see some humor on the board for a change
Think i found the problem on my new old parts rig.
I went back to ten meters were i had half the output and no alc reading
As i pushed down hard on the driver tube the watts went up to 90 watts
out and i had a Alc reading[grounding ???]
I do not want to remove the board so i am going to spray some cleaner
into the socket [after it cools down]
and blow it out with a straw as that's all i have on hand hi hi
As now i don't have a parts rig to fix my Ebay special,i am now on the
hunt again,if the price is right.

Don I had same conundrum of how to peak the 10m driver coil with no ALC reading.

On my 520SE - as with your parts rig - all bands were fine apart from 10m. Inspecting the coil pack I could see the 10m driver ferrite core was deep down in former, not at top where theservice manual says it should be. Once I unscrewed the slug to near top of driver coil forme,r ALC sprang to life.

I now get full scale ALC on all bands with fairly modest carrier level. 10m needs drive cranked up higher, but it's very nearly full scale.

Do a visual on the driver coil to see where the slug sits.

Other suggestion is to install another driver tube. I know you did this to restore 40m but that puzzles me - my understanding is that driver tube 12 BY7A performance fails first at highest frequencies.

Unless. like me, you paid $1,750 for it plus shipping from Guam and the "mint condition" Valiant arrived in six separate, unmatching and irreparable pieces with missing power and modulation transformers and the seller turned out to be an untraceable con artist from Nigeria, it would probably be best if you kept your good fortune to yourself, Bill.

Oh -- what the heck. Go ahead (sigh)...

Hi Adrian
Thanks for your reply
I will indeed check that out too
Something could have happened to the board when he removed and reinstall
the band coupler.
I did have one final tube with the guide broke off the under side of the
tube were the tube fits into the socket.
This is not uncommon for the center plastic guide piece to break off,and
a bit of crazy glue
cures the problem to get it seated back in the socket correctly.
This has nothing to do with the drive problem,but thought i would
mention it as i see no other way to fix it.

Here's a handy tube socket cleaning tip (if I do say so myself). Go to the dental care aisle of your favorite pharmacy and pick up a package of those tiny nylon "interdental brushes." When moistened with DeoxIT, they are perfect for scrubbing out sockets.

Here's another tip,for circuit board cleaning or what ever as i have found so many use's for them.

Next time you go to the Dentist or hygienist,ask them if they? have any instruments that they use to clean or check your teeth with,that they will be deposing of.

They will put them in their radiation machine to kill all the bacteria,and you are good to go,as after so many uses they just throw them out.

They work great on cleaning and picking around solder joints on your circuit boards,and if you get brave you can try cleaning your own teeth hi hi

Don,
If you remove the AF board, there is a small panel you can remove to
get to the bottom of the RF board.

43994. TS-530 Final Compartment Issues

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-12 22:36:44 UTC
From: n5xjt@ymail.com
Topic: 43994 Message: 43994

While replacing the cathode and screen resistors in my previously used TS-530 I found the copper enameled wire on theh Final Choke has come unwound about three turns and the end is just hangin loose. Does it attach under the plate cap assembly or just glue back to the coil? If glue back, will "krazy glue work? Also, someone has removed the Earth Plate (the V shaped piece) under the Final Choke. Is this a problem? Thanks for any help you can give.
Joe - N5XJT

43995. RE: [TS-520_820_530_830] cleaning PCBs in place.

Craig,

Can air is far better and drier in my experience. I remove all my boards and soak them in detergent use sometimes might put it into ultra sonic bath, (depends on board). I usually leave for about an hour, if they are really dirty. Once I remove them I give them a good flick dry and then use canned air.

Now word of caution, do at own risk to your health, I then borrow XYL's hair dryer and blow dry both sides, anything up to 20 minutes, this always works. No matter how I try to avoid XYL temper she always knows I've used it, even if she's been out when I did it. Might have something to do with drying out multiply communtators from prop pitch motors?? Well she got a new hairdryer.

As p[er Ken's site they look like new and you don't have to deal with gummy crap

Dave

VK5PDL

After installing accessory CW filters in my TS-830S, I decided to finish
my extensive refurbishing of this fine and fully operational radio with
a final cleaning of cracks, crevices, nooks and crannies with the aid of
my nifty air compressor. I did this outdoors and, in full sunlight,
observed a disturbing sight. Tiny but numerous rivulets of liquid
emerged from secret hiding places on my RF Board. Now, I had cleaned
the bandswitch contacts with DeoxIT as a first step in the "get it
going" stage of the radio's service (it was pretty much dead as
delivered). However, I had applied the cleaner sparingly using a tiny
brush and a syringe on the individual contacts. I had done no wholesale
spraying of the red stuff. Apparently, however, a previous proprietor
had showered the board with a contact cleaner of some sort (given its
color, seemingly not DeoxIT).

I would like to flush this stuff off the board along with the congealed
dust slurry it's formed. I was able to remove some of the mess with
compressed air and Q-Tips, but much remains tucked away amongst the
densely packed board components. Is there ANY way using ANY agent that
would allow me to safely flush the top side of the RF Board while it is
in place? Yes, I know I could remove it, soak in in a mild detergent
solution, blow dry it and let it sit in the sun for 7 months, but --
honestly -- I hate to disturb something that's working by removing and
replacing if there's a safe and efficient alternative.

Has anyone performed such an operation?

Thanks again,

Craig

Bob:

Another thought came to me.

Probably the easiest and fastest thing to do would be to just make the corrections to the current TS820 Service Manual steps and not completely reformat and rewrite it. Would need some grammer corrections/additions to make more sense out of some of the steps and correct the technical errors and provide missing info.

I would be willing to share any info I have and to serve as an SME and would then try to run the revised procedure in it entirety on my TS-820S before we would make it available.

With what Mark Gilger has collected and my notes and yours and Joes info/experience this might be something we could take on without a lot of work like a complete reformatting and rewrite would take.

Jim Showker also states that he now has a lot of TS820 experience so by now he has had to encountered all the problems and resolved them and marked up the service manual. Perhaps before embarking on this we should ask him if he is planning anytime soon to be offering a revised manual on his website anytime soon. If not perhaps he could provide you with a marked up copy or his notes.

If you like we can take this off the forum to discuss including possibility of revising or creating service bulletins in lieu of the service manual.

Are you saying the end is disconnected from top of the plate choke where parasitic suppressors are mounted to top of the ceramic coil form?

If so, that is 900vdc hanging in the air! CAUTION!

Need to unplug the rig and let is set for awhile and then take a alligator jumper lead and discharge the HV filter caps.

You will need to remove the enamel coating and rewrap this lead at the solder lugs and resolder it. Can remove the enamel by using open flame or better is to drag it thru molten puddle of solder while applying some pressure with solder iron tip. That will then remove the varnish and tin the bare copper. Not easy to do unless you remove the choke and do it on the bench.

Can apply some clear nail polish to the top of the winding. Q-dope would be better but I dont think GC makes it anymore. I make my own from melting styrofoam peanuts in acetone, but clear nail polish will be fine.

I forgot to mention that the "earth plate" is to provide a good rf ground for the metal circumferential shields at base of the 6146 tubes. This metal shield isolates the control grids from RF feedback. It has its own grd pin 8 at the tube socket but the wide copper spring metal strap at base of choke is a more effective RF ground. Rig will run without it, but I would contact Bob Mansker and see if he has one.

Dave, absolutely good advice with the xly's hair dryer.....Some years ago in Miami they had Hurrican Andrew which later was labeled a category 5 Hurricane. I worked in management at Sears our retailer at the time. There were 3 stores that got flooded and the tech took 25 electronic registers to a warehouse and used a hair dryer to dry them out. All but one was saved and they worked perfectly once he dried them out. John, K5IRK

Right now when I do that the meter goes all the way to the left. My esternal meter shows nothing.

>
> It would be very good if you have a local club close to you that you could ask if there is an experienced Kenwood or boatanchor transmitter person who could help you. No shame in that at all. Always helps when someone can explain and demonstrate.
>
> Lastly when you said you cleaned the relay do you mean you cleaned both relays and/or swapped them? How did you clean them?

I cleaned just the relay on the bottom to the back on the rig. I pulled it out pried off the plasic cover shot it with contact cleaner. Then took some 600 grit emery paper and cleaned the onctacts. The relay does seem to work ok
>
> This is beginning to sound like missing ALC bus voltage via the AGL line which is switched by your aux relay. No ALC bus voltage means no TIF amp signal from the IF board. This may not mean much to you now but if you look at block diagram for transmit and read circuit description can see how SSB signal is produced.

Okay Les, but its not a Kenwood.

One Sunday morning last fall during the football season I saw a classified ad for a Johnson Valiant xmtr. I called the guy and asked the price. "Free, I just want to get it out of my garage". I programmed the DVR to tape the game and made the 90 min drive from my house. When I arrived I found a transmitter in very nice condition. To my surprise, it wasn't a Valiant but a Valiant II.

I, for one, love the stories. That's half the fun. Betcha' even the "objectors" probably wud like to hear, although at some point we should probaby limit the posts to the Kenwood hybrids.

Hi Terry,
Thank you for the response. Yes, the end of the enameled wire has become disconnected and is hanging loosely about 3/4 of the way up the choke winding. I was going to scrape the end bare and solder it to the plate cap, e.g., the final tube connection center which screws to the choke top. I think it goes to the center but not sure. your suggestions about how to prepare it and using clear nail polish are MUCH BETTER and I will use them. My question is still, where does the wire end attach? Does it go to the center of the plate cap which screws to the choke? I think it solders to the circular connector from both final tube caps. Is this correct? I will contact Mr. Mansker and see if he has an earth plate. Your advise is much appreciated as this is "new ground" for me.
Thanks Again,
Joe-N5XJT

OK it sounds like you cleaned the Antenna TR relay. This relay would not cause no ALC indication when trying to peak the Drive control.

You need to clean the Aux Relay on top side of rig to the left of the black power transformer. It is under the VOX circuit board. Remove mounting screws and tip board up to access the relay.

I would clean it by wetting pieces of printer or copier paper strips with Deoxit contact cleaner and pulling the paper through the contacts (both the normally closed and the normally open contacts need to be cleaned) while applying light pressure to the movable armature. You should see black streaks on the paper. Then blow out with canned air.

I would not clean with emery paper. Emery particles are conductive. If you want to file the contacts you really need to use a diamond burnishing tool. GC Electronics makes them and MCM Electronics carries them.

Again I hope you are aware of the shock hazards in this radio and are doing all this work under the hood with rig unplugged and left standing for some time to discharge filter caps.

Joe:

It can go to either solder lug on either side of center. Not critical.

Should have solder lugs on each side that the ears have not been bent over. A u-shaped channel exists where the resistor lead of each parasitic suppressor has been soldered. Reconnect the end of the choke winding where ever it will reach.

While you are there look at the soldering of each suppressor. Take a gentle tug on each resistor lead. Sometimes the resistor lead will pull right out of the solder and leave a perfect round hole. The solder will look sublimated ie greyish in color and not nice shiny silver. It is best to remove old solder and apply new if you find this condition.

Also while there take a look at the bypass capacitor and small right angle VHF choke at the base of the main plate choke. See if any discoloration or even the capacitor body can be split.

Ken K4EAA and Jim Hybrid Restore sell rebuild kits.

Can remove the enamel by using open flame or better is to drag it thru molten puddle of solder while applying some pressure with solder iron tip. That will then remove the varnish and tin the bare copper. Not easy to do unless you remove the choke and do it on the bench.

Topic: 44009 Message: 44009

To the group, some GREAT ideas have been posted.

As a reminder, CANNED AIR IS NOT AIR, it is usually canned freon. The chemical is TOXIC and acts like cyanide gas. Oder-less, tasteless, colorless and will NOT make YOU SICK. It will KILL you.

ALWAYS USE this stuff in a well ventilated space.

My son was cleaning a computer with CANNED AIR in IRAQ, Camp Ramadi, 6 years ago this month. He was a communication specialist. Two armed guards.

My son is buried in Arlington National Cemetery. Because of CANNED AIR and not being in an open space while cleaning the PC. A tragic accident. http://wmsinc.org/

Be careful guys.

Dave, absolutely good advice with the xly's hair dryer.....Some years ago in Miami they had Hurrican Andrew which later was labeled a category 5 Hurricane. I worked in management at Sears our retailer at the time. There were 3 stores that got flooded and the tech took 25 electronic registers to a warehouse and used a hair dryer to dry them out. All but one was saved and they worked perfectly once he dried them out. John, K5IRK

Hi,
The 6146A and 8298 has a slightly lower plate dissipation to the 8298A, 6146B and S-2001, it works very well for SSB and CW.
So I did not have any problems at all during the operation.
Best 73's.

Subject: [TS-520_820_530_830] 8298 tube in Kenwood hybrids?

Has anyone tried a type 8298 ("ruggedized" 6146A) in his 530S or 830S?

Anything untoward occur?

Thanks,

Craig

44011. YG-455C vs. YG455C1 filters

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-13 16:21:11 UTC
From: Craig Roberts
Topic: 43994 Message: 44011

I am attempting to outfit my TS-830S with an original "Gold Line" filter lineup. The pair of SSB filters are already present, of course, and I have a YK-88C on hand. What I need now is the YG-455C. I know that Inrad sells a compatible can, but I also see occasional (and less expensive) listings for Kenwood/Trio YK 88C1 devices. They look as if they might be YG-455C filters mounted on a plug-in adapter to fit the later model Kenwoods, meanin gthat I could remove teh filter from the board and have myself the 455 KHz filter I need for my 830S.

Is this so, or is the YG-455C1 a different animal altogether?

I am not dissing Inrad in any way, mind you. I have outfitted a scary number of my old Drakes and Ten Tecs and Heathkits with them and they are superb filters. I am just trying to save some bucks and maintain originality, for whatever that's worth.

Thanks again,

Craig

Thanks very much, Young. That's good news. 8298s (and 6146As) seem to be considerably less expensive than domestically produced 6146Bs and more readily available, too. I would think the effect of a handful of fewer watts output would be negligible and a linear could stil be driven nicely, if desired.

Although --- I must say that I am pleased with a bonus achieved last night by installing new HV caps in my TS-530S. The output power increased by about 5 watts or more (108 vs. 100 at 225 mA on 20 meters, for instance). Again, there's no practical difference on air, but it speaks to the same, juvenile part of me that demanded that I ride a 193 hp Superbike rather than the more sensible 650cc commuter machine my wife owns.

I think what I'll do with this output wattage "bump up" is back off my plate current to 200 mA and baby the finals a bit more.

This is from http://www.k4eaa.com/faq.htm site

Kenwood Hybrid Transceiver FAQ

Do I have to perform any alignment after changing the driver tube?

Replacing the driver tube changes tuning enough that the rig can usually benefit from a realignment of the RF board. Different tube capacitances will shift the tuning on the Rx mixer and Tx driver stages. It's usually not severe , and in worst case you will notice that the DRIVE peaking on receive doesn't match the DRIVE tuning for maximum ALC. A realignment will correct that, and line up the receiver preselector with the transmitter drive peaking once again.

To check if you need an alignment, select a Band and Frequency (tune in a calibrator signal) of interest, and then don't change either during the test. Turn on your calibrator, and peak the S-Meter with the DRIVE control. Then, with the rig in TUNE Mode, flip the send switch and peak the ALC indication. If the drive control is in different positions for Rx and Tx, then go back and check your calibrator signal in receive, and see how many S-units your receiver has been degraded. Your judgment will determine if it is worth going through an RF board alignment.

Gentlemen,
Butch Lewis (KØPSA) here. I'm a retired airline pilot and am fairly new (2008) to the hobby. I am enjoying learning to repair these Kenwood radios. I currently own a 520S, 820S, 830S and a 940SAT. I am in the process of replacing the cathode resistors on an 830S belonging to a friend of mine. The resistor replacemnet is no issue but while looking the radio over, I found the clear pointer on the plate capacitor control to be reversed with the raised portion of the clear pointer facing aft towards the radio face. My friend told me that while attempting to tune up on 20m he could only find a slight dip in the 80m postion of the scale and at that point the main fuse,and the cathode resistors I assume, failed. With the rotor completely unmeshed the clear pointer is indicating 15m. Is this approximately correct? Since the pointer was installed backwards I am suspecting that it could also be 180 degrees out of position. Is this a valid assumption? I could compare it to my 830S, which I may eventually end up doing, but before I take it out of the circuit and take it apart for visual comparison I thought I'd ask if any of you know off hand approximately where the clear pointer should be with the rotor completely unmeshed, or fully meshed for that matter. Looking forward for your assistance.

Butch,

I could be wrong but this sounds a lot like a broken/cracked band switch coupler between the long band switch shaft and the band switch wafer assembly inside the final amplifier enclosure.

Do NOT loosen and/or remove the band switch knob on the front panel!!

To check the coupler, disconnect all power, allow the capacitors in the 830 to discharge to zero, then remove the 830 from it's cabinet (top and bottom).

Place the 830 up right with the front panel facing "your left".

Remove the top cover on the final amplifier enclosure.

Remove the 6146 tube closest to the forward portion of the final enclosure. This will allow you to look closely at the band switch coupler to see if it is broken/cracked.

If the coupler is cracked/broken, you can order a replacement from Ken, K4EAA, at his website

k4eaa.com

If the coupler is in fact broken/cracked and you can order a replacement from Ken, there is a simple procedure you must perform in order to get the long band switch shaft and the final amplifier switch assembly back in "sync". Again, do NOT remove the front panel's band switch knob!! The band switch has a detent but it does not have a stop so the band switch can be rotated a continuous 360 degree without stopping.

First let us know IF the band switch coupler is in fact broken then we can work on getting the new coupler installed and the band switch aligned properly. Again, this is if the coupler is in fact broken/cracked.

Butch, you might best remove both 6146 final tubes when inspecting the coupler. You also should clean the inside of the final cage, fan blades etc, while you have the final cage cover \off.

Gordon

I removed the cover under the AF board ,which was real easy to do,and it saved time,plus no disturbance to the RF board.
Kenwood thought of everything when they designed the TS830,well all most everything.
Thanks for that tip

I have purchased four Kenwood hybrids in the past few months and two of them had cracked couplers. So, Mike's advice is right on. I would replace the nylon band switch coupler even if it is not cracked at the moment. It's a vulnerable piece and replacing it as a bit of preventative maintenance will give you one less thing to worry about.

You can also order brass replacement couplers from Jim Showker (hybridrestore.com). Both he and Ken are terrific sources of parts and expertise -- and both are really nice guys.

Trust me. I love my Kenwood hybrids but, for service and maintenance purposes, I have been spoiled by the very easy to remove vertical plug-in boards in the Drake TR-7.

Oh, and I must compliment my old employer, The Heath Company, for adopting the same scheme for the Heathkit SB-104(A) and HW-104 transceivers.

(Yes, I worked for Heath but -- it must be noted by the hard core technicians among us who have answered my series of dumb questions -- I worked in the marketing department, not the design and engineering group. Can ya tell?)

Jim:

In your original post (pasted below) you stated that the rig transmits always in CW mode but not in SSB. IS THIS STILL TRUE? CAN YOU LOAD THE RIG IN CW MODE? DO YOU GET ALC INDICATION IN TUNE MODE WHEN PEAKING THE DRIVE CONTROL?

If that is still true then you need to ask the person who is advising you that you need to change the Driver Tube how the tube could be good in CW mode and not in SSB mode.

"I just got a Kenwood TS-520S and figuring out how to work it. I have got the tuning down, I am using K4EAA procudures. The problem is that some times I will transmit on SSB and some time it will not. I will transmit on CW alway but not on SSB. The meter on the 520 does show some movement but the extenal meter I have show nothing. I can hear the relay in side clicking."

Hi Bill,

It's not that difficult once you have done it at least one time. The difficult part is making sure the final amplifier's switch assembly shaft, inside the final amplifier enclosure, is set correctly.

Before attempting to perform the following procedure, make sure that ALL capacitors have discharged to zero and ALL power is removed from the 530! Do NOT attempt this procedure with power applied and/or the main power cable plugged into the wall outlet!!! Don't assume the cable is pulled from the wall outlet, check it to be sure!!

Position the 530 on the bench with both top and bottom cabinets covers removed, and the front panel facing YOUR left.

Remove the final amplifier enclosure top cover.

Remove both final tubes.

Look closely at the final amplifier's band switch wafer switch shaft inside the final amplifier enclosure, NOT the long band switch shaft. You will notice there are 2 flat spots on the switch assembly shaft. These flat spots must be positioned exactly as stated below.

Do NOT loosen the coupler set screws until instructed to do so. Also NEVER loosen the band switch knob set screws during this procedure!

The band switch can be rotated a continuous 360 degrees without encountering a mechanical stop. There is a "detente" (click) that is part of the final amplifier band switch assembly shaft inside the final amplifier enclosure but, again, there is no "mechanical stop" in the band switch..

Once you have found the 2 flat spots on the final amplifier switch assembly shaft, inside the final amplifier enclosure, rotate the band switch knob so the 2 flat spots are positioned "exactly" as follows:

1. One flat spot is positioned "exactly vertical" and facing to the "right" (facing the final tubes)

2. The other flat spot is positioned "exactly horizontal" and facing down towards the chassis.

You must ensure the flat spots are positioned exactly as stated above!! Do NOT second guess/assume they are, look closely to ensure the flat spots are position exactly as stated above!!

Next, loosen the "coupler" set screws closest to the long band switch shaft then rotate the band switch knob so the knob is pointing "exactly" at "10" on the front panel band switch setting. The "10" on the front panel is "30 meters" NOT "10 meters"!!!! Rotating the band switch knob should rotate the LONG band switch shaft ONLY!! Tighten the coupler set screws.

Recheck to ensure the switch assembly inside the final amplifier enclosure has NOT moved and that the flat spots are exactly as stated above with the band switch knob pointing to 10 (30 meters) setting on the front panel.

Replace the final tubes and test by tuning the transmitter into a 50 ohm dummy load. If you did it right the 530 transmitter should be working fine now.

I can't stress the importance of positioning the flat spots on the final amplifier switch assembly shaft, inside the final amplifier enclosure, as stated above.

Removing a cracked/broken band switch coupler is not difficult. Loosen the coupler set screws on both ends of the coupler . Gently PULL the LONG shaft outward from the coupler enough that the coupler can be removed. You may have to use your fingers when gently pulling the long shaft to support each band switch wafers on the RF unit board. Do NOT pull the shaft completely out of the radio. You only need to pull the shaft out and away from the coupler enough so the coupler can be removed. It's not difficult, just take your time.

The same procedure is used for the TS-830.

From: Wes Will
Topic: 43966 Message: 44030

Well, got started on the V7A, the first step in getting the 520SE back on the air.

It was running about "too hot to touch" temperature if you plugged it in and flipped the switch. Nothing smoking, but yowch! Hot chassis, and I mean heat hot not electrical potential.

I suspect maybe a blown diode and power supply filter cap could be the cause of that bit of excess heat. So hit that the traces on the PC board were cooked off and lifted where the diode was soldered on.

I'm rebuilding the traces with hookup wire, calling it as practice for if there are missing spots on one of my 520 boards.

Now, if all the high-precision resistors in the divider (mounted on the switch) are still somewhere in tolerance, I might get somewhere. Checking the rest of the thing, removing all the excess solder and flux, and re-soldering about half the joints on the board and the switches, because some prior bone-head used 1950-era plumbing solder (nearly 100% lead) on there instead of electronic-grade silver-bearing solder. And about a pound of flux. Sheesh.

It's a wonder this thing ever worked. (I'm having a lot of fun.)

I'll be replacing the rectifier board in the 520 tomorrow night, if the VTVM works after I'm done.

Wes:

Brings back memories. Heath made a big deal about it having a new fangled PC board in it when they introduced it!

You mention "Diode" so you know it has been modified from original Selenium rectifier. Perhaps at that time they also replaced the filter cap? Might want to measure the plate voltage of the 12AU7 tube. Should be approx 70vdc. Sometimes when folks replace a selenium with a silicon rectifier diode they do not install series dropping resistor/surge current limiter. Have to play around with the value. Maybe start with 50 ohm 5 watt.

As is now it will transmit in CW but not USB.
When I tune up in every thing looks fine.
I switched the relays with not efect
I put in a new 12BY7A that did nothing. This was some thing I thought at begining trouble shooting.
I have tried cleaning contacts in some of the switches.
Jim
I am now looking for some one local to help me.

Jim:

Are you saying it now transmits in LSB?

If so, it sounds like that the USB Carrier Oscillator is not running or you have bad Xtal filter. More likely to have bad solder connection at the crystal pins or bad crystal on the Carrier Osc board than a bad IF filter.

When you turn the mode switch from CW to USB to LSB the switch contacts are applying 9vdc to switching diodes that selects the proper Carrier Oscillator crystal. Not often have bad mode switch contact, but could try cleaning it.

Easiest thing to do requires some test gear like RF probe VTVM/DMM, or O-scope, and/or Frequency Counter and to measure the Carrier Oscillator signal at the input of the Generator Board.

With Mode switch in USB you should measure approx 1.0rf volts @ 3396.5khz at the CAR terminal wire wrap post on the Generator Board. CAUTION: You will be withing reaching and touching distance of the 900vdc at the HV filter caps so exercise caution connecting test equipment to the CAR post when making this measurement.

Hi Mike,
Thanks for the advise on the band switch coupler. I inspected the coupler and found it to be intact and aligned correctly however the forward most allen screw on the coupler was slightly loose. I snugged it which removed the small amount of play. While I have the covers off I am going to replace the plastic couplers with the brass ones. I did find upon close inspection that the coupler on the load control had been glued. I'm still looking for information on where the clear pointer on the plate control should be relative to the rotor position since it can be mounted two different ways on the shaft. I guess I'll just have to take my 830S out of the circuit, open it up and visually check the rotor and pointer positions of the plate control. I'll post my findings so that anyone facing the same issue in future will have a reference.

Butch,

I could be wrong but this sounds a lot like a broken/cracked band switch coupler between the long band switch shaft and the band switch wafer assembly inside the final amplifier enclosure.

Do NOT loosen and/or remove the band switch knob on the front panel!!

To check the coupler, disconnect all power, allow the capacitors in the 830 to discharge to zero, then remove the 830 from it's cabinet (top and bottom).

Place the 830 up right with the front panel facing "your left".

Remove the top cover on the final amplifier enclosure.

Remove the 6146 tube closest to the forward portion of the final enclosure. This will allow you to look closely at the band switch coupler to see if it is broken/cracked.

If the coupler is cracked/broken, you can order a replacement from Ken, K4EAA, at his website

k4eaa.com

If the coupler is in fact broken/cracked and you can order a replacement from Ken, there is a simple procedure you must perform in order to get the long band switch shaft and the final amplifier switch assembly back in "sync". Again, do NOT remove the front panel's band switch knob!! The band switch has a detent but it does not have a stop so the band switch can be rotated a continuous 360 degree without stopping.

First let us know IF the band switch coupler is in fact broken then we can work on getting the new coupler installed and the band switch aligned properly. Again, this is if the coupler is in fact broken/cracked.

I am curious... how would it work in LSB if the Mic gain was turned down?

Mic gain, turning off the processor, and trying different microphones was addressed several post back. Was told all of this was verified.

Original report was good TX operation in CW mode and intermittent TX operation in both LSB and USB modes.

Now it appears it works in LSB?

44037. Re: [TS-520_820_530_830] Re: cleaning PCBs in place.

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-16 13:26:42 UTC
From: Craig Roberts
Topic: 43958 Message: 44037

A few days ago I asked if anyone had found a safe and efficient method of flushing contact cleaner "overruns" and other unwanted gradu* off the component side of printed circuit boards "in situ." It seems that an air compressor stream directed on my TS-830S's RF Board had dislodged ancient rivers of "dust sludge" (old but still liquified contact cleaner residue from previous generations combined with dust, dirt and grime) and I wanted this crud gone without removing, bathing and replacing a perfectly functioning board.

Our friend Don Allen replied:
> "The best I've found for this application is Techspray Precision
> Plastic-Safe Universal Cleaner."

Thank you, Don!

I received my 10 oz. aerosol can of this magical stuff yesterday, immediately hauled my TS-830S with DeoxIT soiled RF board outside, removed the radio's covers and went to it. Tilting the transceiver on its side to facilitate runoff, I flushed the top surface of the board liberally, but carefully using the spray nozzle "straw." Within 30 seconds or less, the RF board was absolutely spotless, dry and looking like new. As Techspray advertises, this chemical leaves no residue and apparently does no harm to components. As proof, the radio fired up normally a few minutes later and I worked an S51 (Slovenia) with a 59++ report immediately (the DX facilitated by a squeaky clean RF board, no doubt :-)).

As Don intimated, Techspray Precision Plastic-Safe Universal Cleaner is not inexpensive. Plus, it's a little hard to find in single can offerings. But, it's worth the effort and expense if you wish clean the surfaces of your radio's PCBs in place quickly, easily, thoroughly and safely.

I'll let you know if the transceiver explodes in a week or two.

/* People from south Louisiana already know what "gradu" or "gradoux" (pron. "grad-DOO") is. For the rest of y'all, it's a mysterious and unwanted substance. The residue on my circuit board is one example. Belly button lint is another, as is the moldy gunk in the bottom of the coffee cup you forgot to wash a week ago. Then there that weird, greenish gray furry thing in the back of your refrigerator that may have been a tomato, peach, mushroom or live rodent a year ago. That's also gradu. /

Hi Butch,

The plastic indicator should be installed with the flat side out - toward the front of the radio. With the plates of the capacitor fully meshed, the indicator should be pointing to the nine o'clock position. With the plates completely open, the indicator should point to the three o'clock position. If these positions are not correct, loosen the shaft coupler for the capacitor and adjust accordingly.

Hi Dick,
Thanks so much for the information. That's exactly the information I was looking for. I did reinstall the clear pointer with flat side out and the pointer is about 30-40 degrees off when the rotor is meshed or not meshed. With your information it should be fairly easy to adjust the pointer so that it points to the correct band when looking for the dip.
Thanks again.
73,
Butch Lewis

Hi group,

I purchased the TS-570 3 months ago and wondering what is a good mic for the rigs. I currently have a stock mike and a Kenwood MC-50.

Rob

From: Mike McHugh
Topic: 44043 Message: 44043

Just turned on my 830s and not much working.....I can adjust the volume but NO display. No signals. Band change knob does not seem to do anything...Mode switch (itself) seems to make some differance but meter does not react to anything. Meter will go FMD when RF control turned all way down.Punching all other switches and turning all other knobs makes no changes...Meter illumination dims when I turn the heater switch on so I will assume the filaments light up.
Disconcerting to say the least. Anybody have an idea where I should start looking????HELP....

Craig,

Congatulations on your success with the Techspray Precision V cleaner.
Albeit a bit expensive, it works very well.

No is is not work in LSB
I have found someone local and have dropped it off to him.
Thank to all the help that you all have gave but I do not want to get it to it and make it worse.

Terry:

That's a good idea, although my first job out of college involved rewriting a lot of manuals and as a consequence I have yet to see one that I like. My standards probably are too high!

I think as first step we should go through the TS-820 Kenwood Service Bulletins, discard the ones that we think are not useful, elaborate on the ones that are useful if required, and add new ones.

And over at Mods.DK there have some useful mods or fixes listed, and some might be suitable for inclusion as well. I can think of at least one that probably is - a frequency instability problem associated with a bad cap in the carrier unit. I did not have that problem, as it turned out, but I put the fix in anyway.

On the other hand, I fixed a problem in the PD unit, replacing a cap, that was a case of something that is in the Service Bulletins but in reality was not broke - BUT the way I did the fix induced teh very problem it was desigend to fix!

It will be difficult to not turn the revised Service Bulletins into a new troubleshooting list, but that's not a bad thing - eventually we will need that, too. That probably will require some reorganization, once we get it fleshed out

So I'll get started on this.

And we need to start a new thread!

Mike: wow, I hope that never happens to my '830.

At the risk of sounding redundant, unless you are well known to our
experts, it would be useful for you to state:
Your access to test equipment, such as a VTVM with RF and hi-impedance
probes. Am o-scope dummy load, maybe a tube tester, or known good tubes,
maybe a good frequency counter and a calibrated watt meter
Good service and owner manuals for the TS-830
Your level of experience troubleshooting and working around LETHAL High
Voltage

Good Luck !

Topic: 44052 Message: 44054

You do not need an RF generator to do the calibration. Start with the rig on for maybe about 20-30 minutes or so...just to get
everything nice and warmed up and stable. Make sure that the "RIT" is OFF!!! Turn "function switch" to "CAL -25"...rotate main tuning knob...until you hear a tone.. that should be the "marker/cal" signal...depending which "MODE" you want to cal...USB, LSB, or CW refer to the markings above the main tuning
knob. Rotate the main tuning knob back and forth through the tone several time to get the feel of it...then using the above mentioned markings,
zero beat..(no tone) the marker signal. If the dial scale...that the silver ring with the numbers on it...just behind the main tuning knob is NOT on an even
25kHz marking...hold the main tuning knob and move the dial skirt until it does. The dial skirt is a friction device and should be stiff..but not hard to move.. and
most important...does not move real easy. If rig has a CW filter installed...see the directions under section 4.4 as mentioned.
This is basic calibration...and you'll need to get used to doing it, as the VFO is not quite linear from on end to the other.

Man its like pulling teeth here. Your last response said it transmits in CW but not in USB.

At one time you said it transmitted in both LSB and USB intermittently.

That means you key the mic and speak into it and get ALC indication and RF output power indicated on your wattmeter from time to time but not every time you key the mic. Perhaps the use of the term intermittent was not correct? If you get just a small/short duration flick of ALC and output power that is not intermittent operation. That is momentary operation.

It really helps to understand what the real operational issue is.

If this fellow has problems I offer this final thought.

1. In CW you need Carrier Osc and dc voltage from the Car level pot to produce output from the Balanced Mod. If you have good CW output into dummy load then you know you have these two things.

2. In LSB and USB you need Audio and Carrier Oscillator input to the Balanced Modulator. This means two different Carrier Oscillator signals and not likely that both would be missing, but very easy to check at the CAR post on the Gen Board. Audio is needed at the BM post (approx 150 to 200mv for full scale ALC indication). Again very easy to measure.

3. You said you tried a different mic and set mic gain full CW and no results. It is possible that you have a bad front panel mic jack connection but not a very common failure.

4. Tell this guy after loading in CW to turn off the SG switch, place mode switch in LSB/USB, remove mic and set mic gain full CW and then flip to Send. Now touch finger or tap a jumper lead to the bottom right pin on the mic jack. Should get full scale ALC deflection as he taps this pin. (assumes he has no way to inject any kind of audio test signal). If no ALC deflection then go to the Phone Patch jack on rear panel and touch center pin there(assumes this is a TS-520S). If you get good ALC indication it means you have a bad connection on the front panel mic jack. If no ALC indication then need to measure Audio and Carrier inputs at Gen Board.

5. As I mentioned he should find approx 100 to 200 mv of audio at BM and 1.0 volt of Carrier at the inputs to the Balanced Mod on the GEN Board.

Good luck

Do you need a separate email mailing list for this? NOT one of these annoying wahoo thing-ummies, just plain email in from one, email out to all?

I run a mail server, with the Mailman mailing list server. It's the work of a couple minutes, without raising a sweat, to set up a private mailing list. Anything up to about 250 users won't even be noticed. (More users than that, I'd need more bandwidth if the amount of message traffic was significant.)

There is also an FTP server on here, I can give you all access to it, one username, one password for everyone to use to dump files for collaboration. Same deal, two minutes, no perspiration for me, and the machine and connection costs me the same if it's sitting idle or running full-out. (Apache web server as well, but that's not presently set up for easy access from outside of my internal network, it would take me probably half an hour to tweak it.)

Just an offer, thought it might be handy.

Good morning Bob..... Ok on your note.... I do have scope and multimeter.... LOT of in field troubleshooting experience. Carried tool kit all my working life. NCR corp. Dumac Corp. Amtec corp. POS and Microfilm and pc etc.etc. Yup, know all about HV and dangers.... I know you are trying to help (and keep me safe). This is all appreciated.
I did find the problem after the knock testing of the plugs and boards.... Turned out plug #2 on counter unit board X54-1540-00 was intermittent. When I "knocked" on that connector ALL functions came back to life....WHEW!
I proceeded to Exercise ALL plugs on the rig.....After 30 some years guess the ol-girl has right to be a little cranky...Love her though...Just like the 520s I also have.
I was Amateur in the 50's (WA2AMZ). Just getting back to it and FUN. Challenging as well. (This issue).
Thanks, again. All responses are greatly appreciated......

Wes:

I will leave that up to Robert. I hope to just be a worker bee on this project! I cant even spell DOS!

One of the things that kept me from just correcting the steps in the 820 Service Manual is I couldnt figure out how to scan it in and convert from PDF to a format that I could make the corrections.

That and I had envisioned a complete rewrite in a different format perhaps similar to the TS830 matrix with a little more meat on the bones which would take some time commitment.

My 520s "seems" to operate fine. I say it this way because I do not have anything to compare it to. I don't know if anything has ever been replaced, nor when the last time it was aligned. I have almost nothing in the way of test bench equipment at the moment.

Can anyone recommend a shop/person that can do an overhaul/alignment and maybe caps? Just want her tip-top before winter.

Mike:

This is good background and should serve you well. Just dont get offended if anyone forgets this over time. Number one objective is to make sure no one gets hurt.

As to exercising all the molex connectors in the rig there are at least two camps. Some recommend it as a first step along with cleaning relay contacts and spraying copious amounts of contact cleaner. Others say only when "knock test" or troubleshooting indicates connector is the potential problem. There is risk of inducing new problems in these old rigs so just go into this with your eyes wide open. Very easy to pull molex connectors off the board. Also wiggling side to side can produce crack at foil trace to pin pad and induce an intermittent and very hard to see and find.

When I have to unplug one I try to pull straight up and only rock end to end if any rocking at all.

I once pulled three off a customers IF board and set there with tears in my eyes. I called Ken Kempski and he shared similar horror stories with me. Only good thing was when I removed board to repair I found much cobble work with numerous traces repaired with jumper wires etc.

Customer opted for a "new" replacement board from Bob Mansker.

Enjoy your TS830

TJ:

Is this rig new to you or one you have had for some time?

Before you send it off for a tune up suggest you read Section 6 of your operating and instruction manual. Start with Paragraph 6.3. The steps listed there will allow you to tune up the Receive and Transmit performance of your radio to pretty close to design specs with no test equipment required.

Just skip the steps that call for test equipment.

If you have never performed Coil Pack alignment and dont have the proper alignment tool come back and ask about the precautions and some steps to make this easier.

You can test the Receiver performance where you are at now by turning Marker signal on and peaking the Drive control around 1200. Do this on each band at around 200 on the VFO. You should see approx S9 on all the bands except perhaps 10 meters where will see S6 or so.

You can test the Driver stage by placing SG switch off and seeing if you can get maximum ALC indication in CW mode and the indication not falling off quickly. Do this on each band. Should get FS ALC deflection with Car Level pot advanced no more than approx 1000 to 1100 with exception of 10 meters which may take 1200 to 1300. Let the Driver tube rest between bands. Dont leave rig keyed for more than about 10 seconds max. Drive tube runs Class A and will get pretty warm.

Can then load into Dummy load to approx 200ma IP and should see approx 100 watts output on all bands with exception of 10 meters which may be around 80 watts or so.

Regards replacing HV filter caps these are the only ones I recommend replacing under preventive maintenance umbrella as they can cause collateral damage and make a real mess when they fail.

If you do not feel comfortable after reading Sect 6 then by all means ship the rig off. Just be sure you understand how to professionally pack so it survives the round trip journey.

44068. TS-820 Service Bulletin Rewrite

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-17 19:38:28 UTC
From: Terry Wagoner
Topic: 44068 Message: 44068

Robert:

Started new thread. Couple of questions.

You already know what I think about TS520 "No. 21 Service Bulletin". Kenwood would never direct a tech at authorized service center to replace Q4 3rd IF mosfet to address No Receive condition. There are one line entries after one line entries like this that an experienced tech would laugh at. Obvious exceptions include:
1. Q4 was speced wrong and not correct device for this application
2. Q4 was installed wrong at factory
3. Q4 was from a bad production run of mosfets

So with that back ground we should be able to draw lines thru many of these kind of recommendations on most of the Kenwood "service bulletins".

Question then comes what do we replace them with? I think we need to define who the audience is that we are writing for. Is it the newly licensed and first time Kenwood Hybrid owner?

Kenwood factory engineers would have written for a technician who had a good fundamental electronics knowledge back ground, good experience level, and good trouble shooting experience including knowledge of test equipment and how to use it. Very seldom are any technical manuals, service manuals, service bulletins, or maintenance procedures ever written for the owner/operator.

We can write for the newly licensed owner operator if that is what is needed. Might eliminate a lot of the repeat questions on the forum in absence of a FAQ section?

So how rudimentary do we want to get? Do we want to include operator error items?

With the example of No Receive above do we want to replace the recommendation to replace Q4 IF Amp mosfet with a series of steps or do we want to write a Troubleshooting Guide for Weak and/or No Receive conditions?

Here is example of steps that we could use in place of "replace Q4":

1. No Receive (all bands)
A. Check Antenna switch is off ground postion and switched to an antenna
B. Check RF gain full CW and AF gain turned up
C. Check Remote Plug 8/9 jumper
D. Check Xvtr switch off
E. Check RF attenuator off
F. Check Function Switch to VFO

And/Or things like:
G. What does Marker signal do? If good Marker then problem is before Coil Pack board.
H. Clean contacts and/or swap Aux relay and T/R relay
I. Measure 9vdc regulated and RF-1 3.5vdc at AF-AVR Board

J. Measure AGC bus voltage at RF board Conn RF-1 Pin 7 (use 11meg meter should read approx 3.0vdc)
K. Check L8 Antenna Step-up Transformer. Do we tell them how to test it or how to jumper around it?
L. Remove and clean Molex connector RF-1 on RF board
M. Remove and clean Molex connectors IF-1 and IF-3 on IF board.
N. Measure DC voltages at RF amp Q2 (DSG voltages)
O. Measure VCO level at TP on RF board. Should be approx 1.0rms rf volts.

I think you get the idea.

Perhaps there are some things suited for a Service Bulletin and others for a Trouble Shooting guide?

Maybe how to install jumpers in the DG-1 vias is Service Bulletin material and how to trace signal path and signal levels thru the Counter Mixer board is Trouble Shooting Guide stuff?

Terry K9TW

44069. Strange problem

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-17 20:27:33 UTC
From: W5RKL
Topic: 44069 Message: 44069

This problem is not in a Kenwood hybrid. I thought this problem would be an excellent learning tool for members who are studying vacuum tube theory.

The transceiver is a Heathkit SB-100 5 band ham transceiver consisting of all vacuum tubes. Power is supplied by an HP-23C separate supply.

The symptoms are

1. S meter pegs below zero
2. Meter zero pot has no affect on meter
3. Receive and calibrator signal levels have no affect on meter after 3 minutes of warm up
4. Receive audio, whether from off the air signals or tuing the 100Khz interval of the calibrator (Marker for hybrid owners) is distorted

What's the source of the problem? Don't guess, use the information provided to determine what's causing these symptoms and the source of the problem. For those who know already, sit back and let the inexperienced members work the problem. Do NOT worry about whether you get it right or not. The important thing is you learn something from this!!!!!

First, let me give you some voltage measurements. I like voltage measurements, they allow one to learn how to use test equipment plus they give you 'clues' as to what the source of the problem could be!!!

Measured all power supply voltage, bias is -117VDC, LV at 317VDC, and final amplifier's HV is "825VDC", all measured in receive and all are normal as measure in the transceiver NOT at the power supply output connector!!

Transceiver is in receive. This is NOT a transmitter problem, it's a "receiver" problem so don't think anything "transmit", think only "receive" and vacuum tube theory. If you have an HW-101 or SB-101 schematic you can use them, the HW-101 and SB-100/101/102 series transceivers were basically the same. There are difference between these transceiver and I know the VFO in the SB-102 is all solid state so no need to bring all that out. The point here is the IF amplifiers in all of these transceiver is the same.

The S meter (meter switch set to ALC, required to display receive S Units or transmit ALC levels) displays variations in V3's screen and cathode voltage. When V3's screen voltage decreases, V3's cathode voltage increases causing the meter to fall back towards zero (more positive potential on the meter's negative terminal and less positive potential on the meter's positive terminal). If V3's screen voltage increases, V3's cathode voltage decreases causing the meter to rise

above zero (less positive potential on the meter's negative terminal and more positive potential on the meter's positive terminal). Simple metering circuit based on the voltage changes on V3's screen and cathode. If V3's cathode voltage rises higher than normal and V3's screen voltage decreases more than normal, the meter will fall below Zero due to the higher positive potential on the meter's "negative" terminal and significantly less positive potential on the meter's positive terminal, the meter will stay put below zero until the problem is solved. The meter zero pot is there to equalize the voltages applied to the meter terminals so with no signal received the meter rests at zero.

IF amplifier's V3 and V4 are both 6AU6/6AU6As which are sharp cut off pentodes typically used as RF and IF amplifiers.

Following are voltage measurements taken at the first and second IF amplifiers, V3 and V4, when power first applied. Note the voltages, you will need to know them later on to help you diagnose the source of the problem and what's going on in both amplifiers!!! As I said above, use the information provided so you can diagnose the problem. Don't guess, you won't learn a darn thing by guessing!!! Don't quickly say, replace the tubes, again, you won't learn a thing doing that. Remember, I have said many times, NEVER replace a component unless your troubleshooting results tells you to, this problem is no exception to that!!!!

The following voltage measurements were taken when power is first applied to the transceiver.

Measured V3s plate voltage which is +305VDC (normal)
Measured V3's screen voltage which is +195VDC (normal)
Measured V3's grid voltage which is -1.07VDC (normal)

Measured V4's plate voltage which is +304VDC (normal)
Measured V4's screen voltage which is +253VDC (normal)
Measured V4's grid voltage which is -1.07VDC (normal)

After approximately 3 minutes the S meter drops and pegs below zero. The meter zero pot has no affect, meaning you can turn the meter zero pot till the cows come home and the meter will still be pegged below zero!!! Nope, cleaning the meter zero pot is a waste of time, the symptoms do not change cleaning the pot so put the can of DeoXit D5 back on the shelf!!!

Let's see what going on here, take some voltage measurements again but concentrate on V3 only this time. V4 is affected but not nearly as bad as V3 is. Read later below to see how V4 is affected by V3's mess:

V3's plate voltage is NOW +195VDC"
V3's screen voltage is NOW +145VDC
V3's grid voltage is NOW "+1.7VDC" (Definitely NOT normal, normally this should never be positive!!)

Hmmm, some major changes in voltages have occurred!!! Remember I said V3's grid should never go positive, well it did!!! We have to determine

"why". Comparing the initial normal voltage to the now "changed" voltages should give you clues as to what's going on now. So why is the grid of V3 and V4 changed to a positive voltage? The key is in V3 plate and screen voltages.

Notice V3's "Plate voltage"!!! It has dropped significantly from "+305VDC down to "195VDC". That's a difference of "110VDC"!!! Also notice that V3's screen voltage has dropped by 50VDC. Just those 2 voltages alone tell you that V3 is conducting into saturation. What's causing this to happen and why V3's grid is positive? Excessive gas in V3. The gas positive ions produced in V3 collect on the grid of V3. Electrons are attracted to those positive ions so electrons emitted from V3's cathode, race toward V3's grid causing grid current to flow in V3 which is how V3's grid changes from a "negative" voltage to a "positive" voltage. When this happens, V3 conducts heavily into saturation causing V3's plate and screen voltages to take a dive and V3's cathode voltage to rise significantly higher than normal which causes the meter to drop below zero.

Okay, now that we have determined what the source of the problem is, what is causing the distortion in the speaker? When V3 goes into saturation and grid current flows in V3, the output signal from V3 is "distorted". V4 also has a slight amount of grid current, not caused by gas in V4 but rather caused by the high positive grid potential from V3 imposing on the AGC buss. V3 and V4 use the same AGC buss so any positive potential appearing on the AGC buss shared by V3 and V4, will affect both tubes. Correcting V3's problem will eliminate V4's indirectly induced problem as well.

Since both tubes have grid current, V3 more than V4, both stages have distortion in their outputs. The distortion in both tube's output combines is amplifed and pass the amplified distorted signal on to the Product Detector. The Product Detector doesn't care about distortion, it simply mixes the distorted amplified IF signal with the CAR Generator signal (BFO), passing it's "distorted output" which is the recovered audio, on to the audio amplifier, hence you hear distortion in the speaker. Eliminate V3 and V4's problem (distorted output) and you eliminate the distortion heard in the speaker.

Replacing V3 solved the all the problems.

This is an excellent example of how taking voltage measurements, comparing them against normal voltages, and having a solid understanding of vacuum tube theory is so important. I hope you learned something from this.

@Terry: I picked up the TS-520s as part of a LOT sale about 6 months ago. I fired it up and it worked, so I began to use it as a primary HF rig in the shack and took my Alinco DX-70T out to the truck. I had not played with tube/hybrid rigs since my novice days, so this was a blast from the past and a chance to re-learn some forgotten knowledge. I am in the beginning stages of rebuilding a proper test bench. Until then I have a GOOD digital multimeter, MFJ-259B for RF SG and Freq Count (no dip coils yet). A few cheapo tuning wands and that's about it.

I will give the Section 6 a once over and let you know how I feel. Feel free to supply the "precautions and some steps to make this easier" anytime.

Thanks, 73, TJ, K4TFJ

44073. Re: TS-820 Service Bulletin Rewrite

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-18 00:26:38 UTC
From: roberteleazer@rocketmail.com
Topic: 44068 Message: 44073

Terry:

I view Service Bulletins as an addition to the service manual, the service manual modified by real world experience. In the case of the Kenwood SB's, they are essentially additions to the troubleshooting guide.

In comparison, the Heathkit Service Bulletins are a bit different. They can be an addition to the troubleshooting guide but often they basically say something like, "We initially put 6146B's in the HW-100. They worked fine. But they were all GE 6146B's and it seems that any other company's 6146B's may very well not work well at all. Damifwenowhy. But if it's not a GE tube, use a 6146A; they all seem to work Okay."

The Kenwood SB's are far less definitive. You do not know why they are saying what they do. A bad batch of parts? A change in vendors? A typo on the schematic? A process error in the factory? Good old Saburo the tech retired and nobody else was as good as he?

Anyway, I think we should write a new list of Service Bulletins with the end objective to eventually create an entirely new troubleshooting guide to replace the one in the manual entirely. In the interim the new SB's will be an addition to the troubleshooting guide.

For example I would envision one that said:

"X. Frequency instability:
a. Dirty cap in the VFO (may produce total dropouts as well as jumps of up to 500 KHZ)
b. Low 9VDC supply voltage (can cause anything you can imagine).
c. Bad cap that filters the 9VDC in the carrier unit (1-2 KHZ back and forth oscillation NOTE: Mods.DK has a mod on this I have performed)
d. Some fool replaced the tantalum cap in the PD unit with a ceramic one (1-2 KHZ back and forth oscillation) or else the tantalum cap is just bad.
e. ?"

Now, if we had nothing to say about frequency instability because it is not an observed problem, then that would not even be a category in the New Service Bulletins, but obviously it is one.

As to whether we include stuff like "No Transmit: SG switch off" and "Rig lights up but is inoperative: No 9 pin plug installed" - I donno, but I doubt it. Maybe we need a "Before you do anything else check the following items" section. Even if newcomers to the Yahoo group refused to read the files first at least then we could just do a copy and paste to respond.

I have done little radio stuff over the last few months because I have been working on my airplane. The company came out with a couple of Service Bulletins that turned out to be a real bear to perform ☐ and even worse, proved to be real, valid concerns, even more so than they realized.

Best regards,

Robert

44076. Re: TS-520s Alignment/Overhaul

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-18 02:23:41 UTC
From: Terry Wagoner
Topic: 44065 Message: 44076

TJ: OK so not a long history where you might notice some decline in performance.

Well just perform the RX and TX performance tests I provided and read Sect 6 and decide. It really is pretty easy to do a decent Coil Pack and IFT peaking using the Marker signal as your sig gen and the S-meter as your peak reading meter.

As to some precautions look around page 38 of your manual depending on revision and you should see picture of the vertical mounted boards. Het Osc, Mixer, Antenna, and Drive coils to give you an idea of what you are looking for.

With rig unplugged for some time and covers removed lay rig on its top with front panel facing you and these coils will be on the front left side of the chassis. With good light and perhaps magnifier take a good visual on them. Sometimes the cardboard coil formers will be twisted off there mounts and windings/turns may even be slightly unraveled. This is due to stuck core and someone torqued too hard on it and twisted the former from its mount.

Take good look at all the slug tuned cores. If you have any cracked these will have to be removed and replaced. This can be a pain and may have to break it up or drill/grind it out carefully with a Dremel tool burr and shop vac out the pieces and powder. If new core is now too loose in the form I wrap it with small amount of PTFE plumbers tape. You can ask on forum if anyone has any spare cores or contact Bob Mansker. Some folks report good luck with using cores removed from scrap CB radio coils.

If you dont have the exact plastic alignment tool order one from Ken K4EAA website. Do not use any kind of metal tool to try to turn the cores with. The ferrite material is very brittle. You may want to apply a small drop of WD-40 or lite oil at top edge with a toothpick to each core before starting the alignment. Some report good luck with Ear Wax removal/softner oil from drug store. I have never tried it.

If you encounter any cores that will not turn freely after a pre-lube stop and do not force it. You can apply heat from tip of small soldering iron to the core and it should free it.

Important to do the alignment in exact order specified. I usually do it with rig on its side so can see S-meter as turn the cores. Just have to be aware that energized HV filter caps are nearby and must control fingers and tools to ensure no accidental contact.

Hi Mark:

Agree would be nice, but I think it would be easier to first develop a bench tested written troubleshooting procedure first before you can flow chart it. Seems like it would be easier if a two step process? Maybe not? Any event a lot of work. I have seen some nice flow charts for things like Tek O-scopes.

Mike:

Darn-it dont you hate it when that happens! You arent becoming the absent minded professor are you? Fun to do these kind of exercises and relate them to our Kenwoods. Thanks for sharing this.

For any of us the did not see that the teacher told us that the control grid voltage was going positive as rig warmed up and it was in this case due to "gassy" tube we surely deserve an F on our report cards.

I guess might want to give another reason that grid voltage could go positive....a leaky interstage coupling capacitor. Pulling tube and monitoring AVC voltage at control grid pin at tube socket should eliminate that cause. In old days would lift one end of cap and place VTVM on the lead and power the rig and should see a momentary flick upwards on the meter as the small value cap charged. Might never would see it with DMM. Depending on the value of the capacitor may take as much as 8 time constants to decay back to zero so for a .1uf cap and 10 meg meter it would take approx 8 seconds for voltage to decay back to zero. It takes very little leakage current (in the microampere range) to throw the bias voltage off. 1 microampere might give you .5vdc change.

Where does this gas come from that the electrons are striking and turning these gas molecules into positive ions which are then attracted back to the cathode (where they can strip it) and to the control grid causing it to go positive in potential?

Tube is under very high vacuum. However not possible to get all gas (atmosphere) out of it when it is pumped down and sealed. Also there is entrained gas in the tube elements and coatings and insulators. The high vacuum is tugging on these materials pulling the gas from them as they are heated during each on cycle. Also the pin seals at the point where the elements leave the glass envelope can develop very small leaks allowing atmosphere to be pulled into the tube.

This is where the Getter comes in. For a flash getter it is made of highly reactive metal usually barium. In presence of this heated gas it reacts with it chemically to remove it and/or thru adsorption. So the getter has a life. It is being expended over each heat cycle. If you see the getter has white powder around it then likely you have a major leak at the tube pins and the getter is fully expended and the tube is no good.

Sometimes you hear people say the tube is "Leaky" or has "Leakage". That is not the same as "Gassy". I have been guilty of using the terms interchangebly. Leakage is the microampere leakage current path across insulating barriers and supports between the elements. When you are using a tube tester to check leakage you are measuring the dielectric strength of the insulating materials such as the insulting film between the heater and cathode. A good tube will have insulation values in the 10s of millions of ohms. You dont want any current flow due to what is effectively a short between the elements.

When you are using the Gas test feature of your tube tester you are not measuring presence of gas directly you are measuring grid current. Exactly what Mike was trying to drive us to

answer. Gassy tube causes grid current between the control grid and cathode because the grid has now become positive with respect to the cathode due to these positive ions collecting at the grid and charging it positive.

Lots of very good old tube manuals available on the web. I like the manufacturers manuals from the 40s and 50s.

I look forward to Mikes next problem of the week. Not sure how he will tell who is holding up their hand! Major points off for blurting out the answer!

Robert:

This thing seems to be taking on a life of its own! If Service Bulletins are extensions to the Troubleshooting guides where are those guides?

My recollection goes back many months ago when I noticed a thread about a fellow trying to null the carrier and he was adjusting the trimmer cap and trimmer pot at the Product Detector and not at the Balanced Modulator because he was trying to follow the directions contained in the TS820 Operating Manual.

We talked about errors in the Operating Manual maintenance section depending on what revision you were using. We also began talking about the Service Manual and the many gross errors and admissions in it that caused much frustration. Much discussion then about the need to revise the Service Manual.

I remarked that I had a marked up service manual but could not say I had found all the errors. I am not an expert. I have probably worked on 25 or so 820s over a 10 year period so hopefully have encountered most of the problems trying to use the documentation. I wrote an example of a proposed service manual revised step and posted it. I dont remember what message number it is. Got very little feedback as I recall at that time.

Now we have evolved to Service Bulletins and Troubleshooting Guides.

As far as Operating manual goes about 3 errors I know of that can be easily fixed. As far as the Troubleshooting guide contained in the Operating manual I simply ignore it as it is designed to mainly address the brand new owner/operator error type items with gems like "if SSB speech is garbled switch the mode switch to the opposite sideband". I would not waste 5 minutes working on it. With the Forum an owner really doesnt need to refer to it.

The Service Manual is primarily intended to provide instruction on how to align and calibrate the radio. Can also help with troubleshooting as it does contain some signal levels, dc voltages, RX/TX Level diagrams, and x-ray views of the boards. It is really intended for the experienced tech or ham who has troubleshooting experience, test equipment, and experience using the test gear. Evidence of this is how so few owners understand and use the TX level diagrams to troubleshoot low or no RF drive. Where as experienced bench techs rely heavily on rf voltage measurements to identify where the fault is.

Service bulletins as you say should be factory produced and issued based on post production operating and maintenance experience. Lessons learned communicated back to authorized service centers for their use in servicing and repairing customer radios and in some cases addressing gross errors that require a recall.

Mods originating from the factory should be contained in Service bulletins and most that I have seen are more commonly driven from the owner operator conceived and implemented ones that are listed in various websites and survival guides. Do we really need to install star lock washers on all board hold down screws?

Detailed Troubleshooting guides and flow charts. I know of none? There has been some interest expressed in a DG-1 guide.

The Yahoo Kenwood Forum. A source of all information. How to operate. What accessories fit what rig. How to align and calibrate. How to troubleshoot. Preventive and corrective maintenance. How circuits actually work. Signal levels. Tips and techniques. All often repeated over and over and over again. How to load, how to neutralize and how to replace and align bandswitch coupler comes to mind.

If I was a new owner I would have to ask myself...What revised TS820 documentation would I find the most useful to me at this time?

I will try to help in any capacity that I can. Just not sure revised Service Bulletins will do the most good for the most people but I will be glad to review any strawman you produce and if it requires running on an 820 I can do that on my rig.

44081. T-599D question?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-18 15:19:50 UTC

Topic: 44081 Message: 44081

Hi,
Does anyone know what VR09 (1K) is for on the T-599D, it looks to me like it comes off the generator board through R27 (100 ohm) to ground? I found it to be the cause of intermittent power/tuning issues on my 599D.

I can't find a service manual for download (seems like every other manual for the 599 series is there but that one, unless I'm missing it)

I dont see that particular resistor in the plain 599 service manual.

It's been a long time since I've done any trouble shooting on a rig and it shows. I recently retired and have a new found interest in the hybrid rigs. I love the 599D twins, but would also like to get a 530 or 830 (preferred) in order to have the warc bands. My main interest is cw rag chewing.

Thanks in advance for any info on the variable resistor in the 599D.

The R599S Service manual was mean for the D + S
series as it was told to me. I think the 'S'
series was meant only for the Japan market. You
can find both on W6WK's web site. Or jump to it from the following link.

Good luck.

44084. Homebrew digital display for the Kenwood TS-520s

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-18 17:05:33 UTC

Topic: 44084 Message: 44084

Proof-of-Concept <http://youtu.be/GyTHEPcFe-I>

This is the early stage of a digital display for the Kenwood TS-520s using an Arduino Mega2560 and some supporting circuitry. The DG-5 display normally used for this family of rigs can be hard to come by in good shape and/or expensive. Additionally I included the ability to send the frequency and mode information via the USB serial to a computer for logging. It is emulating a Kenwood TS-50 for the communication to the logging program. This is still mostly in a proof-of-concept stage.

44085. KENWOOD HYBRID USER NET (August 18th, update)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-18 18:32:18 UTC
From: mvgilger
Topic: 44085 Message: 44085

The Saturday's net on 40 meter was run by Jimmy, WB2KNR. He had 8 stations checking in under good band conditions. Jimmy indicated this was the first time he can remember when there were zero TS-520's checking in. I have to agree. Very unusual. Out of those, there was:

0 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
3 running TS-830S
0 running TS-900

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 8 stations checking in under good band conditions. Out of those, there was:

4 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
1running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87

March 2013, Saturday's, net total = 112, Sunday's total =39
April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 45, Sunday's total = 50
June 2013, Saturday's net total = 30, Sunday's total = 27
July 2013, Saturday's net total = 63, Sunday's total = 41
August 2013, Saturday's net total = 48, Sunday's total = 35 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Pete, the pot in question is labeled as "VR9 1K" and is located on the T599D schematic at the top right end of the X52-0009-00 board in series with a 100 ohm resistor to ground.

More than likely that pot is very dirty/corroded which is causing the
intermittent problem. Clean the pot then test.

Q5 is the 1st Mixer it takes low level IF signal and high level VFO (LO) and mixes them and produces your 8.8 mhz TIF output. It is your TIF amp same as in the hybrids. The TIF signal is fed to the TX Mixer and mixed with Het Osc to produce the output transmit signal that is fed to control grid of the 12BY7A Driver tube. All standard stuff here.

Q5 is a FET mixer with a bypassed source resistor. This means if you increase the value of VR9 trim pot you will reduce the gain and lower the output signal level. It is similar to cathode bias with a tube. According to the voltage table in the manual in TX mode you should see approx 0.95vdc on the Source of Q5 in TX mode.

I am not sure why they wanted a variable source resistor? I dont think the input level to the Band Pass Filter would be too critical?

We need TX level diagram to know what the input level to the BPF should be. Not sure if these exist for the T599? In the TS520 the TIF signal level at output of the BPF is approx 250mv rms. If you have no means of measuring RF level than I would just measure the source voltage to chassis and if approx 0.95vdc should be good and if not tweak VR9 until you get 0.95vdc in TX mode.

With approx 250mv of TIF and approx 1 volt of Het Osc you should have approx 2vdc rms at output of the TX Mixer.

Best way to troubleshoot weak or missing Rf drive is with RF millivolt meter or O-scope and see where you are missing the signal.

I forgot to mention DO NOT mess with T3, T4, T5 BPF coils. You cannot just adjust them for peak RF output. These need to be stagger tuned to give proper TX bandpass response and must use Sweep Gen and markers to adjust these.

I am sorry one last thing and I will get out of the way. If the trim pot is bad and you cant find a replacement just replace it with a fixed resistor. Could select one to set .95vdc on the source of Q5.

Makes no sense to need a pot unless they were getting batches of 3SK22 mosfets with widely varying forward transfer admittance? Similar to vacuum tube transconductance. I dont think very likely?

Terry,
Thanks for the responses, that's what I did to fix it temporarily. I didn't measure the voltage I measured the value VR09 was set to and used an equivalent fixed resistor. Probably not as accurate but the transmit intermittent issue is fixed anyhow.

Not sure what happened I posted this info earlier but I don't see it here in the thread anywhere.

I did already and it didn't help, it must have a hairline crack or something. I measured the resistance that it iwas currently set to which turned out to be approximately 600 ohms and just replaced it with a fixed resistor as a temp solution. The radio works fine now but I want to find out why it was there in the first place and adjust it for whatever the proper setting was supposed to be. It is on my T599D schematic but I'd like to find it in a service manual to see what to adjust it to. All the T-599 service manuals I can find don't show it, the only place I can find it is in the schematic in my 599D operating manual.

Thanks
Tim

Terry,
I suggest the KISS approach.
Just a referenced list of Operating and Service Manuals error corrections and see how that goes.
Probably a one pager.

Unlikely that Service Manual would describe how to adjust this trimmer. I would have guessed something around 300 ohms. Problem with measuring value at the set point is you never know if any former owner had tweaked it. If you get time suggest you measure source voltage key down.

I would prefer to include measuring the TIF signal level. If you have O-scope can measure it at the Out terminal on the board. As I said should see something like 250mv rms or approx 700mv P-P @ 8.595mhz.

I looked for Service Manual and TX Level Diagram and couldnt find one.

OK if it was a snake I would not be typing! Found manual under my nose on Gordons site.

I dont see VR9 adjust discussed. Also, it does not have TX Level Diagram but does have active device voltages under heading of Battery Chart Table 2. It shows RF voltage at OUT terminal to be 0.5 but does not say if it is rms. My guess is that it is as they also show VFO signal to be 1.0 rf volts and that would be about correct for an rms LO level. So 500mv is about twice the TIF level that I am use to seeing. Kind of unusual to have the RF level to be half the LO level.

TS820s remote VFO outlet cap issue

I have purchased the REMOTE VFO cap/plug so I can jump pins 8-9.

Who has one of these plug/caps? How do you get the cap off the plug. Simple question/issue but sure has me stumped. I do not wan to damage the plug.

Although the K4EAA K1 knob is no longer available, and certainly a bit pricey used, it doesn't come close to the price of a TS-830S on the used market. I've seen nice 830S' go for as much as $500 to $600. And, I'm not talking about eBay either, but QRZ, eHam, and QTH.

Original KB-1 knobs almost never go for less than $100 and I have seen them go for $200 on Ebay.

Ken Kempski replica K1 knobs can command $100. I would like to have a pristine KB-1, but not willing to mortgage the house. Kens knobs are just fine. I have Kens dark bronze knobs on my 830s and unfinished ones on the VFO-240s.

I plan to experiment with home anodizing on the unfinished ones. Need to find source of scrap 6061 aluminum to experiment with. Ken had tough time finding an anodizer around Sarasota/Tampa area that could match the Kenwood KB-1 color and provide consistent finish between batches.

Topic: 44081 Message: 44102

Thanks again Terry,
I measured the value when the tx was not exhibiting the problem, came up with that value (about 600 ohms) and put a fixed resistor in place to see if it fixed the problem. It did. Today I'll get a 1k VR at my local surplus store and replace it at a set value of 600 ohms. The radio has been operating normally ever since the replacement of the suspect pot. I'll just operate it as is until I find some concrete info as to its purpose and adjustment values. I appreciate the help from all who responded and commented. Now to find a nice TS-830 to add to the mix.

The plastic Kenwood OEM knob can be filled from the back with a mixture of epoxy cement and lead shot to give it a nice heft and weight. No, you won't have a a sexy KB-1 knob, but you'll save $100 or more. (The idea comes from my friend Bob Sullivan, W0YVA).

Be sure you balance the lead shot (or whatever you use for ballast) or you
be cursing the autorotating knob that refuses to stay put!

Its fundamental purpose is to set the bias on the FET. The question is why did they see the need to make it variable instead of the more traditional fixed source resistor (typically around 300 ohms) that you will see in the Kenwood hybrid FET based mixers?

A source resistor sets the self-bias. Using a source resistor is the simplest and most common form of FET biasing. If you buy a batch of 50 MPF-102 FETs they will all have varying Id drain current perhaps by as much as 10% which means varying transconductance. So instead of installing different values of fixed source resistors (which are cheaper than trim pots) I guess Kenwood thought faster/easier to have person on assembly line tweak a pot to set Id for each 3SK22 that was installed. Since Id not easy to measure maybe they monitored Mixer output level and tweaked the pot?

Maybe your production number is a proto-type T599?

I have virtually no hands-on experience with T599. Be curious to know if other production runs using a 3SK22 FET have a single fixed resistor and no pot.

Where are all the retired Kenwood design engineers? Are none members of this forum? Sure would be fun to pick their brains.

Greeting group,

  yes, the original KB-1 knobs are great...but way too expensive...Ken Kemski's version is excellent and, a good
price...too bad it's not being produced.

  To weight a knob..I have used 3 fishing weights. They are small...shaped like a long football...and have rubber on the
ends...which makes for a good fit, and easily removed/modified..if you screw up. They are about 1/8 to 1/4 oz each.

Original KB-1 knobs almost never go for less than $100 and I have seen them go for $200 on Ebay.

Ken Kempski replica K1 knobs can command $100. I would like to have a pristine KB-1, but not willing to mortgage the house. Kens knobs are just fine. I have Kens dark bronze knobs on my 830s and unfinished ones on the VFO-240s.

I plan to experiment with home anodizing on the unfinished ones. Need to find source of scrap 6061 aluminum to experiment with. Ken had tough time finding an anodizer around Sarasota/Tampa area that could match the Kenwood KB-1 color and provide consistent finish between batches.

I checked my T-599D last night. I have no pot (VR09) in mine so it agrees
with the service manual. There's just a 330 resistor from the FET source
to ground.

I did this to my 830 tuning knob back in the 80's. I had a source for steel ball bearing so I filled each knob section with them. Added or removed to get good balance and then added some epoxy to hold them in place. Been working fine ever since.

Thanks Pete

Appreciate you taking time to do this. Makes more sense for a fixed resistor and 300 ohms is more typical of the values in the hybrids. I have looked at all the gain controlled devices and mixers in all the Hybrids because I was interested in why they kept increasing the RF-1 level (from 3.2 to 3.6 in the 830s) thus raising the DC control voltage to the gate 2 of the dual gate mosfets and increasing the gain of the RF and IF amps. Around 4 volts you are pretty much at the knee of the curve for the devices Kenwood is using. I made a chart of device numbers for each RF and IF amps and each Mixer. I included the source resistor value and whether bypassed or partially bypassed.

Also, there was a fellow promoting a mod to lift gate 2 off the agc bus and take a 10k current limiting resistor and jumpering from drain to gate 1 to turn RF amp mosfets on hard to improve receiver sensitivity. He had made no measurement on the effect on Sig to Noise, 2 signal, or blocking performance. In fact he ignored what this would do on 160 and 80 where strong signal abound. I dont think he realized that all the hybrids other than the 520 had a gain control circuit that cooled off the receiver on 160 thru 15 to improve strong signal performance and ran them hot on 10 meters where signals at the antenna would be weaker. All he had to do was buy or make a high gain directional antenna for 10 meters.

I guess we will never know why some T599s had this trim pot in the source lead. Only thing I can think of is to address differences in production runs of 3SK22 mosfets? Seems silly to me.

Yes people have been adding shot to VFO knobs for as long as there have been VFO knobs and as you say if done well and balance is kept in mind not a thing wrong with it.

Some claim it causes premature front bearing or bushing wear, but I doubt it as at the very low rpm we are talking about there just isnt any vibration to worry about. I would worry more about the imbalance causing VFO to drift off frequency before I would worry about bearing or bushing loading and wear.

When we are spinning a 100 ton rotor at 3600 rpm then eccentricity and vibration is a big deal for the bearings.

I do this procedure slightly differently, forgot who showed me. But here is how I do it, if it helps.

Set mode to TUN
Set function to 25KHz.
Set your band as needed. (I will use 40m and 7.200 for this example.)

I will tune around 7.200 until I hear the marker. It will be noticeable because you will hear a dip in the tone as it goes away and then comes back. Make note of where it is at and move the outer ring of the main dial to correspond to 7.200 using the center mark between LSB and USB. Now hold the outer ring from moving while you tune for the center of the dip. This can be determined by watching the s-meter. Tune real real slow.... watch the s-meter peak, then start to vibrate. That is now dead on the marker. Release the outer ring. Turn off the 25KHz.

I can make a video of this procedure if you want.

TJ, K4TFJ
Comments always welcome.

Section 5 of the TS-830S Instruction Manual details the Optional Accessories available for the TS-830S. The KB-1 was designed and sold as an option.

Kenwood engineers would have had to made an error by designing and producing and selling the KB-1 Deluxe Flywheel VFO Tuning Knob. I know of no evidence that this design has proven flawed with long operational experience.

I always assume that the Kenwood design engineers did a pretty good job until field experience has proven otherwise. In that event you would normally expect to see a Service Bulletin to be issued or an optional accessory to be removed from production and sales.

I dont know if they performed laboratory accelerated wear test on any of the Hybrid VFO drive trains or not. I suspect not.

VFOs with the stock knobs do show wear(excess axial and radial movement of the knob)after many many years. I dont think the KB-1 knob would noticeably accelerate that condition. I see stock VFO knobs that wobble like on an eccentric and the current owners are oblivious to it or just live with it.

All radios have a economic design life and my guess is all the Hybrids with stock or optional flywheel knobs have long exceeded that.

I run the K-1 replica knobs and have no concern about accelerated VFO gear train wear. I do balance the wear by using the external VFO some of the time but I am not anal about it. I suspect my TS-830S and the VFOs will long outlive me. Of course my operating time and VFO lock to lock cycling is probably very low compared to average owner.

In addition to owning a 520S and 830S, both with the stock VFO knobs, I own an Elecraft K2 with the N8BX machined bronze knob. The stock K2 plastic knob's weight is 2 oz., and the N8BX bronze knob is 6.5 oz. The K2's VFO uses an optical encoder, unlike the Kenwood hybrids' mechanical VFO gear train. After a couple of year's of use, the K2's optical encoder's shaft bearing is starting to show some wear, and resultant "play." It's not bothersome, or creating any problems electrically, and really not noticeable... unless you really spin the weighted knob where a faint "scraping" noise is heard.

I agree with Terry, I am certain the Kenwood engineers took the weight of the KB-1 knob into account. The KB-1, or a design equivalent, was also used on the TS-780 Multi-Mode 2M transceiver (1982-late '80s) as the stock knob, thus the engineers likely would have taken the knob's weight into account when designing the TS-780.

Tim, You neglected to state what mode you set. The Center mark is for CW where the tone in the speaker = your peak volume in the narrowest filter and on USB or LSB you tune for Zero tone over that mark corresponding to the mode set. (For the 520 rigs at least)

I do this procedure slightly differently, forgot who showed me. But here is how I do it, if it helps.

Set mode to TUN
Set function to 25KHz.
Set your band as needed. (I will use 40m and 7.200 for this example.)

I will tune around 7.200 until I hear the marker. It will be noticeable because you will hear a dip in the tone as it goes away and then comes back. Make note of where it is at and move the outer ring of the main dial to correspond to 7.200 using the center mark between LSB and USB. Now hold the outer ring from moving while you tune for the center of the dip. This can be determined by watching the s-meter. Tune real real slow.... watch the s-meter peak, then start to vibrate. That is now dead on the marker. Release the outer ring. Turn off the 25KHz.

I can make a video of this procedure if you want.

TJ, K4TFJ
Comments always welcome.

44122. AF level on TS-530 S

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-20 12:19:34 UTC
From: Bill
Topic: 44122 Message: 44122

I have a TS 530 s in which the audio level is fine when you first turn it on. After a 1/2 hour it starts to drop in level and you have to advance the AF control. All the voltages are within spec and stay that way. I had a power surge here 3 weeks ago which upset a lot of things. I changed the HV caps (lost HV to 300 volts) and the screen caps and the Cathode resistors to get transmit back up to par. Also had a bad cap on the IF board. C 75 was dragging down the 9 volt supply. Everything else seems to work fine now. Any ideas would greatly help.

@John: I did state I was in the TUN position (see 00:15-00:20), but otherwise your procedure matches the manual. The TUN mode also corresponds to the CW mark, but instead of the 700Hz offset to the lower side only, you can use the valley null to zero. I am not saying this is the proper way, it's just the way I was shown, and it works great for me for a reason.

Maybe I should explain why I use this over the manual's procedure. I had some hearing damage while in the service, both over-all loss and some tonal loss, specifically in the low-low frequencies. By using the valley or dip method on the TUN function, I can watch for the vibration/warble of the s-meter. It is difficult to hear the tone if I attempt this in the other modes.

Besides, it doesn't differ all that much from the manual and the most important thing was for someone to understand and "SEE" that the outer ring of the main dial can be moved (or held) separately. That one fact is not very clear in Section 4.4, hence the primary reason for the video.

That's OK if you STAY AWAY from band edges since you are almost 1K off freq.

As I understand the 520's manual, the TUN mode (CAR) frequency is the
actual center frequency and also used for CW transmit. The CW receive
frequency is actually offset by 700hz and LSB/USB 1.5KHz respectively.
(Reference Table 1, Pg 25). This has procedure has been proven to be dead
on with a few Hz as I have done this many times before checking into nets
and the dial will read correctly, definately not 1KHz off.

I am open to hearing your theory as to why you think it would be 1khz off.

Ken's site leaves the impression that he may restart the K1 knob process. I assume this is old information and it will not start back

I wish I could have bought one. What was his original price? I guess you could do you own replication if you had access to a cnc machine. The price to do just one would be more that one would want to pay.

Brian:

Yes-tooling up for one would be cost prohibitive unless you had your own machine shop.

You might try emailing him and ask if he has any unfinished ones left. About a year and half ago I bought 2 from him that had been blasted but not anodized at a pretty deep discount. He assembled them with the finger hole spinner for me. I prefer he tell you what he sells them for.

I have not spoken to him in some time and my last email went unanswered. I winter in Fort Myers Beach south of him and would stop and visit with him. Saw him last winter and had no contact since then.

He had quite a few at that time. Dont know if he still has them or not. Actually they dont look too bad in natural color, but with time oils from fingers will discolor them. As I mentioned my plan is to try my hand at home anodizing. Igloo cooler, sulfuric acid bath, DC power supply, RIT dye bath (if you like natural clear finish no dye cycle involved). Lots of good info on web on home anodizing. You dont need glycol chillers etc. Look at the simple processes. Just need to practice before trying on the good knob.

If anyone is real serious about bring back a nice
weighted knob for the TS-830, or others, they
might want to contact www.73CNC.com
and have a discussion with them. He's designed
knobs for a lot of different radio's and sets up
at the Dayton Hamvention every year for those that like that.

Give me a break I have never owned a tube rig before. I do not know anything about fixing or working on electronics.

Your last response said it transmits in CW but not in USB.
>
> At one time you said it transmitted in both LSB and USB intermittently.
Sometime it would transmit when the key was down and some times it would not. The key would be down and it would transmit. The next time I would key up it would not transmit that is intermitent.

>
> That means you key the mic and speak into it and get ALC indication and RF output power indicated on your wattmeter from time to time but not every time you key the mic. Perhaps the use of the term intermittent was not correct? If you get just a small/short duration flick of ALC and output power that is not intermittent operation. That is momentary operation.

>
> 2. In LSB and USB you need Audio and Carrier Oscillator input to the Balanced Modulator. This means two different Carrier Oscillator signals and not likely that both would be missing, but very easy to check at the CAR post on the Gen Board. Audio is needed at the BM post (approx 150 to 200mv for full scale ALC indication). Again very easy to measure.
>
> 3. You said you tried a different mic and set mic gain full CW and no results. It is possible that you have a bad front panel mic jack connection but not a very common failure.
>
> 4. Tell this guy after loading in CW to turn off the SG switch, place mode switch in LSB/USB, remove mic and set mic gain full CW and then flip to Send. Now touch finger or tap a jumper lead to the bottom right pin on the mic jack. Should get full scale ALC deflection as he taps this pin. (assumes he has no way to inject any kind of audio test signal). If no ALC deflection then go to the Phone Patch jack on rear panel and touch center pin there(assumes this is a TS-520S). If you get good ALC indication it means you have a bad connection on the front panel mic jack. If no ALC indication then need to measure Audio and Carrier inputs at Gen Board.
>

> 5. As I mentioned he should find approx 100 to 200 mv of audio at BM and 1.0 volt of Carrier at the inputs to the Balanced Mod on the GEN Board.

I finnaly gave up with this rig it went to the electronic recyclers yesterday.

I am trying to help you. You dont need to know much about radio to describe the symptoms.

It is understandable that it may take some follow up and probing questions. Unless we clearly understand what the operational issue is we will waste our time and your time. The answers you provide make all the difference in the world in the quality of the advice anyone can give you.

You would never say to your mechanic that your car wont start sometimes and expect him to point you in right direction. What would that mean to him? It doesnt crank? It doesnt turn over? It fires and stalls? It makes a rapid clicking noise? It makes one click and dash lamps go out? Starter spins fast but does not engage?

I am sorry to hear you gave up on the radio.

If you come back someone else other than this crabby old man will help you.

Terry and our other experienced guys:

I think this is the key here "
Give me a break I have never owned a tube rig before. I do not know
anything about fixing or working on electronics."

An honest answer, and perhaps for the future the first proposed answer
would be to name some repair guy references or maybe a local ham, when
the owner of the rig is simply NOT Qualified to attempt repairs.

I HAVE worked in electronics, sometime professionally, since 1958. I
HAVE owned, built, and repaired dozens of tube rigs. I DO have and know
how to use test equipment. I AM also nearly 69 years old, DON'T see as
well as I used to and DON'T have a lot of experience with sophisticated
solid state rigs that have hard to get parts and inconsistent manuals!!

SO, if my TS-830s ever takes a hit, and it's NOT just a TUBE, she's
going someplace where they know how to fix rigs like this. (I know money
is tight but so is a screwed up useless rig)

You can't be expected to help people with limited knowledge or radios
and or electronics and or without test equipment.

I don't think it's a good idea either, BECAUSE SOONER OR LATER someone
without the proper tools or experience is going to try following a
simple suggested repair or measurement and really SCREW UP BIG TIME and
GUESS WHO HE"S GOING TO BLAME?

Just my thoughts

Terry: For goodness sakes, you don't owe him (is he a Ham?) or anyone else an apology!!! He wants someone to spend hours helping to remotely troubleshoot and fix a 30 year old radio and then complains?

Please read my message copied to the group about some other issues you may get yourself with this type of person

Perhaps the group needs some type of warning caveat such as:

"Since this group is aimed primarily at licensed Amateur Radio Operators, it is presumed that users requesting help have at least a basic knowledge of electronics and repair techniques as well as access to appropriate test devices. Additionally, any and all suggestions, recommendations, etc, are offered in the spirit of Ham Radio assistance to fellow hams and are not a substitute for paid professional work. It is understood that our ability to assist is limited by having no physical access and our dependency upon the requester to accurately describe problems and settings and take correct measurements when requested. In this group offer of mutual assistance, NO LIABILITY for damage to equipment equipment or harm to an individual is provided or available under any circumstance."

Terry please feel free to change or ignore as you see fit

Please share only with Moderator or others OFF LINe..I don't want to start or be in the middle of a 15 shouting match LOL

Tim,

The youtube video helped a lot, I was able to follow your video and calibrate the dial scale.

Thank You!

John

44136. TS-520SE Tuneup Procedure

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-21 03:58:01 UTC
From: John
Topic: 44136 Message: 44136

I have a TS-520SE connected to a MFJ-945c antenna tuner. The MFJ-945c is then connected to an outdoor MFJ G5RV antenna strung between trees in my backyard. I want to transmit on 40m SSB. Can someone describe the antenna tuner procedure I should follow before transmitting?

Thanks!

John

John,

I am NOT an expert, by any means, but have been a ham for MANY years now. To operate a tube rig into a complex antenna like the G5RV, you have to take away some of the variables you have in that system. You MUST tune the finals of the 520 to a known 50 ohm load first, or you will never know where you are. A dummy load is a must for tuning up a tube rig properly, regardless of other circumstances. Once the rig is tuned to the dummy load, you will need only to "touch up" tuning once the tuner is set. I do an initial "set" of the tuner using an MFJ-259B to tune my 80 meter, 300 ohm ladderline fed antenna to resonance at the frequency I want to operate. I MAKE SURE that the antenna load impedance is close to 50 ohms resistive and that the reactance is not some strange value but is close to zero so the rig sees a proper load.

Others will have other "procedures" using different techniques. I have just described my process to protect the tubes, tuner and antenna. Some test equipment is a necessity for operating an amateur station (wattmeter/SWR bridge, dummy load, etc), just check with others and see what has worked for them and try several if you can.
I hope this helps some, surely others will chime in as well.

I do know that Ken spent a lot of time getting everything just right...machining, even anodizing just the exact shade...etc.
  His stock of knobs sold out QUICK! even at $100 a pop.

Ken's site leaves the impression that he may restart the K1 knob process. I assume this is old information and it will not start back

I wish I could have bought one. What was his original price? I guess you could do you own replication if you had access to a cnc machine. The price to do just one would be more that one would want to pay.

I've had similar discussions privately with Terry.

I've made the same observations you have.

My question is "why are inexperienced people buying these rigs? Is it because they are cheaper than modern fully solid state rigs?"

I get the feeling a lot of the people I see on this list and other boatanchor lists are in over their heads.

Terry: For goodness sakes, you don't owe him (is he a Ham?) or anyone
else an apology!!! He wants someone to spend hours helping to remotely
troubleshoot and fix a 30 year old radio and then complains?

Please read my message copied to the group about some other issues you
may get yourself with this type of person

Perhaps the group needs some type of warning caveat such as:

"Since this group is aimed primarily at licensed Amateur Radio
Operators, it is presumed that users requesting help have at least a
basic knowledge of electronics and repair techniques as well as access
to appropriate test devices. Additionally, any and all suggestions,
recommendations, etc, are offered in the spirit of Ham Radio assistance
to fellow hams and are not a substitute for paid professional work. It
is understood that our ability to assist is limited by having no
physical access and our dependency upon the requester to accurately
describe problems and settings and take correct measurements when
requested. In this group offer of mutual assistance, NO LIABILITY for
damage to equipment equipment or harm to an individual is provided or
available under any circumstance."

Terry please feel free to change or ignore as you see fit

Please share only with Moderator or others OFF LINe..I don't want to
start or be in the middle of a 15 shouting match LOL

Hi Guys and Girls,
I would like to Thank everyone that contributes to this group.
Terry and Mike, Special Thanks to you two guys. You go above and beyond and it is noticed !!
I would just like to remind everyone that we ALL were new to this stuff at one time or another. I love seeing the help and the knowledge being shared. I do not feel any question is a "Dumb" question. Asking questions is how we learn.
I encourage everyone to continue to share their experiences and their Knowledge. I remember many years ago when I was afraid to ask a question for fear of being labeled as stupid! I don't want anyone to feel that way! I think it is wonderful that guys want to learn more about their radios and how to keep them going for many years.
I Also want to Emphasize that Extreme caution should be taken when working on these old Radios. There are Voltages in there that will KILL you.
Again, Thank you to everyone for contributing and Thanks to Coors Bill for starting this Great group! RIP Bill !

I really do not want to bash the newbies. But I would like to know why people are starting with complex radios like the Kenwood Hybrids?

My feeling is the problem started with the elimination of the Novice license. When a lot of us stated we built kits like the Heathkit DX-20, Dx-35, DX-40, or DX-60. These are all better starter radios than a complex solid state transceiver.

We combined these simple transmitters with low end communication receivers. Mostly Hallicrafters and Hammerlund. The Heathkit HR-10 is an excellent novice receiver.

This stuff is easier to get working than any of the Kenwood hybrids. But for the most part they are CW rigs. Actually CW/AM.

But they are far easier to get working than a old solid state rig.

The other thing is test equipment. The first thing you need is a decent VTVM and the manual. My preference is most any of the Heathkit VTVMs because they have the best manual. And don't hesitate to buy a good repro manual for your VTVM. If you are not able to repair and calibrate your VTVM you will not be able to repair a radio,

I would still like to know why people with no apparent experience are buying complex radios like the Kenwood hybrids.

One of the first items you need is a set of alignment tools.
http://www.gcelectronics.com/order/catdisplay.asp?CatID=16

Buy a set of these before messing with any adjustments:
http://www.gcelectronics.com/order/SubCatPDF/alignment%20tools%20Kits%20380-387.pdf

Why do people start with a G5RV?

If you start with a simple single band dipole you will not need a tuner with Kenwood hybrid.

Hi
I have recently bought a ts830s because I like old radios. I have only had my licence for 20 months and come from a none technical background, and i find the idea that only people who have an understanding of how it works can enjoy these wonderful rigs abhorrent. It has been a very steep learning curve for me at the age of 64 the brain does not work so fast as when younger but I thought the idea of groups like this was to help people understand and keep these wonderful rigs alive. I will learn how to service and look after it because that is the nature of the hobby but please don't knock those who perhaps have less understanding than yourselves. We all had to start somewhere. Ok rant over does anyone know of someone in the UK who will be able to help with repairs or servicing if I get out of my depth please as most of the expertise seems to be in the States.
73 de Mike 2e0mcy (hopefully soon to be M0??? as just sat the exam)

Bob I think that Kenwood has a great reputation. Their transmit audio has always been terrific. Older radio's appeal to many of us for nostalgia and because there are no damn Menus !!!. To the inexperienced, these and maybe a low price make a tempting combination.

Having said that, many issues are not immediately obvious to those unfamiliar with tube and hybrid rigs, as well as early generations of 100% solid state rigs:

1. Lack of knowledge about pi network loading
2. Frequently less knowledge about electronics, trouble shooting, use and access to test equipment, etc, that was much less the case when these rigs were new 40 or so year's ago
3. Limited or unavailable exact parts replacement
4. LACK OF DEALER SERVICING for these rigs
5. Fragility of old circuit boards,connectors, wires, switches etc.
6. NON-HAMS and intended non-ham use
7. Modified rigs - undocumented

So, they see a nice shiny rig somewhere and they buy it, and it is not PLUG 'N Play, more like PLUG and PRAY !!

Best

Bob/WA2JAJ

No need to drag this out so my final words on it.

1. New people are swelling the ranks and not their fault they are entering the hobby in this era and new manner. In some respects good as it sells gear and hopefully helps retain spectrum. Hopefully something will be done about IMD/splatter specs for new gear or we will get expansion of the existing bands. It is getting ugly.

2. These folks are buying technically complex KW hybrids as first rigs with no fundamental radio electronics knowledge, no experience and/or no test gear because these rigs are readily available and far cheaper than newer DSP menu driven rigs. I doubt there is any thought of how overwhelming and daunting a task they have just taken on.

3. There is no interest in a DX-40 and Knight Kit Ocean Hopper regen receiver or similar Novice stations as no CW ability.

We cannot change these facts. With that in mind Mike and I and others have to accept fact that we will have to play twenty questions and at times it really gets old especially when it becomes apparent that the new owner really has little aptitude or interest in learning. We have a choice to continue to play here or move on.

So knowing all of that:

Number One Priority is....PERSONAL SAFETY. I am very very concerned about that. Mike, Gordon and I have talked about adding a Disclaimer.

Number Two Priority is....Rig Damage and frankly I dont worry too much about this. We all caution about cracking cores, pulling off molex connectors, lifting solder foils, damaging final tubes etc, but most of these events wont relegate the rig to the trash heap.

Lastly, Gordon and I will have to agree to disagree about no Dumb Questions. I do not agree. This isnt about damaging the self esteem of a child. Questions with no effort expended, questions without opening the instruction manual, questions without any interest in the underlying fundamentals (just give me the answer) etc. are in my opinion all "dumb" questions. We have had this debate here before. We are dealing with adults and not bright eyed 6 year olds.

I just need to get smarter and learn to walk away sooner after about one or two follow up questions as by then I have pretty good idea of where things are going. My own fault.

Just got a note from (KD2...) who wants to remain on sidelines expressing his disappointment that the thread on the TS520S with no output in SSB mode will not come to closure. He relates to me that he is a new ham and new owner and has been following the thread by looking at the block diagram and trying to follow along on the schematic to learn how a SSB signal is produced in his rig. Man that is great to hear! It is what the original poster should have been doing as well.

First I need to thank you as you are exactly the kind of Ham that I am here to help. I also am disappointed. The lesson will not come to a conclusion that you can learn from. But not all is lost.

Quickly what we believe is that the rig does have good RF output and ALC indication in CW mode. If this is true then you do know that the Balanced Modulator (fundamental component in SSB transmitter) is getting required Carrier Osc signal (1.0volts) and dc bias voltage (0.0vdc to 0.7vdc) from the Car Level Pot resulting in output from the Gen Board to the IF board.

So what is different about SSB? In SSB the Car Level pot is out of the picture. We still need Car Osc signal (at LSB or USB frequency)and we need Audio signal in lieu of the dc bias voltage to the ring diodes to produce output from the Balanced Mod. So which one or both of these signals are missing is now the question.

In 10 minutes we could have done the simple test I suggested to determine if the audio amp is working. Tap test at mic jack and phone patch jack and injecting some kind of audio at BM terminal is easy to do and tells us if we need to focus efforts on Mic amp circuit or the Carrier Osc board.

The best thing that you can now do for me and more importantly for yourself is to go to older version of the ARRL handbook and read section on Balanced Modulators with emphasis on ring diode type. Can also Goggle on RF mixer and ring diode balanced modulator tutorials. You will learn how they work including the typical signal levels for the Carrier Osc and the AF input.

Also take the time to study the TX Level Diagram in your service manual. It tells you all the RF levels in CW mode at approx 14.2mhz with SG switch off. A valuable tool.

This isnt how you would learn how a SSB transmitter works from classic texts as not in normal progression, but using a rig problem to learn how the circuit works, what the goes ins and goes outs are, and what levels they need to be is a very good way to learn and eventually you can piece it all together.

Suggest you log the typical Balanced Mod input signal levels on your schematic or in your notes for future troubleshooting as you develop out your RF service bench. I have marked up schematics and several 2 inch three ring binders full of notes. Just do better job than I did and at minimum organize info under alpha tabs! A winter project for me someday.

Once again thanks for your email. It sure made my day. You are on the right track. It will just take time. Thirst for knowledge and passion for the hobby will serve you well. You cannot learn it behind the mic or the key. That part is fun, but for me not as fun as figuring out how these things work. Maybe when you get some dollars aside can think about another TS-520S to work on. Really a very big help to have two same model rigs in good trim. When you have problems with one can use the other for comparison.

44149. Recommended Book on Electron Tubes

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

Topic: 44149 Message: 44149

A while back I suggested a website, WWW.tubebooks.org, as a source of basic information. Relative to that website, I posted this on QRZ last night, and I think it's appropriate here as well.

For anyone seeking to improve their boatanchor knowledge, I'd like to recommend what I have found to be an excellent book.

It is US Army Technical Manual TM 11-662, also known as US Air Force Technical order TO 16-1-255, entitled, "Basic Theory and Application of Electron Tubes."

The book came out in February 1952 and does a great job of explaining how electron or vacuum tubes work in an manner that is neither too technical or excessively infantile. I have read up through the Triode section so far.

I have fooled around with tube electronics for about 40 years now, and now, finally, I understand what I know!

The book is available for download for free at www.Tubebooks.org

Here's something that will make us (well, most of us) ill. Ross Distributing in Idaho has been selling off its inventory of parts and accessories for a number of years. He sold his remaining Kenwood KB-1, new in the box, for $36.95.

Topic: 44123 Message: 44151

Well, could be a number of things.

Get a copy of the manual if you do not have one, available free online from various sources.

A dead VFO might do what you say all by itself. By VFO is dead do you mean that the digital display is blank?

Open up the rig and see if the connectors on the back of the VFO are still attached and that all of the connectors going to the various boards are attached. NOTE: LETHAL VOLTAGES ARE PRESENT IN SOME LCLOCATIONS, like that 925 volts HV! If we don't hear back from you we will know that we have lost yet another member of this group.

Then turn the rig over, and check to see if the low voltage DC is present at the AF-AVR board. There should be 9VDC at the connector pin nearest to the potentiometer VR1.

Stay away from the diodes on the bottom near the power transformer, since they can be shorted out very easily, but do note if any of them are burned or cracked.

What about the "volume level"? What do you mean? Is there any noise at all coming out of the speaker? If not, plug in a headset and try that.

Good luck!

There are a number of good reference books available for the inexperienced ham(s) who does'ot have any electronic knowledge/training. One of my favorites is

"The Basic Radio Course" by "John T. Frye"

This book may be available at your local library, at hamfest, used books stores, and on CD on eBay (search ebay for Basic Radio Course). This book is written so the inexperienced/non-trained person can easily understand the subject matter. I highly recommend it.

Another reference is old editions of the ARRL handbooks. Edition from 1975 and older are good choices. These can be found at local libraries, hamfest, and eBay.

Here are some basic electronic questions that you should be able to answer. Experience members please let the inexperience members answer the questions. For the inexperience members, don't "guess" at the answers (you never learn a darn thing by guessing), just answer the questions.

Circuit:
3 resistors with the resistance values of 1, 2, and 3 ohms are connected in series then the series string is connected across the 12 volt battery.

1. What is the total resistance of the circuit?

2. What is the total current flowing in the circuit?

3. What is the voltage drop across each resistor?

4. What is the total power consumed in the simple circuit?

==========

What is the power consumed in a resistor that has a total resistance of 120 ohms connected across a 75 VDC power source?

==========

A relay coil, 12 volt battery, an amp meter, a 12 volt lamp, and a simple switch circuit is connected together as follows:

The "Positive" terminal of the battery is connected to one side of the switch.
The other side of the switch is connected to one side of the relay coil
The other side of the relay coil is connected to the positive terminal of the amp meter

The "Negative" terminal of the amp meter is connected to the "Negative" terminal of the battery
The lamp is connected in parallel with the relay coil.

The switch is turned ON and the lamp glows dim but the amp meter rises very slowly above zero.

The switch is then turned OFF and the amp meter falls rapidly to zero but the lamp glows very brightly for a second then goes dark.

1. Why does the amp meter rise very slowly when power is applied to the circuit?

2. Why does the lamp glow very brightly for a second then go dark "after" the switch has been turned OFF?

==========

These are only a very small sampling of the simple "Basic Electronic" questions you should know and be able to answer.

73
Mike W5RKL

The above basic electronic questions are all part of learning basic electronics.

Bob

Possibly quite simple - the older rigs are cheaper than even second-hand modern equipment. From my own experience, I was looking for an HF rig within my price range. Sure, I'd really have liked an FT-9000 (keep dreaming!) or even an FT1000 or FT2000. But splashing out ?1500 on a new hobby was simply not an option. An older ham (now sadly SK) had a TS-530 for sale. A little googling returned highpoints such as fantastic audio.

What google DIDN'T show was the complexity of the set when troubleshooting. Neither did it really show the "complexity" of using it compared to a solid-state "power on and press the tune button". Neither did my good friend go into detail about that, hi hi. So no, I didn't know I needed probes, oscilloscopes, test meters and the odd sacrificial virgin. Glad I didn't know, might not have bought three damn fine rigs.

But, so what. Its good to learn, and so what if 'novices' are buying the older rigs - if 'experienced'* hams are not buying them, then who will?

*Based on my limited experience, even many M0/M1 (advanced/full/'experienced') licence holders would struggle troubleshooting a hybrid, as their experience is with solid state, and to be frank many study for the advanced exam and then have nothing to do with the more practical side of the hobby, beyond calculating antenna lengths - and I've been asked by M1's for help with this, me, a mere M6 licencee.

Subject: Re: [TS-520_820_530_830] Please help, Don't bash the Newbies

I really do not want to bash the newbies. But I would like to know why people are starting with complex radios like the Kenwood Hybrids?

My feeling is the problem started with the elimination of the Novice license. When a lot of us stated we built kits like the Heathkit DX-20, Dx-35, DX-40, or DX-60. These are all better starter radios than a complex solid state transceiver.

We combined these simple transmitters with low end communication receivers. Mostly Hallicrafters and Hammerlund. The Heathkit HR-10 is an excellent novice receiver.

This stuff is easier to get working than any of the Kenwood hybrids. But for the most part they are CW rigs. Actually CW/AM.

But they are far easier to get working than a old solid state rig.

The other thing is test equipment. The first thing you need is a decent VTVM and the manual. My preference is most any of the Heathkit VTVMs because they have the best manual. And don't hesitate to buy a good repro manual for your VTVM. If you are not able to repair and calibrate your VTVM you will not be able to repair a radio,

I would still like to know why people with no apparent experience are buying complex radios like the Kenwood hybrids.

Start by adding two more items to the mix... a dummy load and a good swr/power meter between the rig and the ant/dummy load.

The procedure I use is: Tune the rig following the instructions in the manual into the dummy load. When done, go back to the TUN mode and tune the ant with the tuner. Switch to CW and do the final tune of the ant and touch up the rig. Done

Bob, I started with a G5RV antenna because it seemed the best fit to cover all the bands I wanted to explore.

As I recall with a simple dipole, I could remove the Antenna Tuner from the equation if the antenna was the proper length for a single band, but I would be limited to the single band the antenna was tuned to.

Bob raises excellent questions. My take is that they've either been told, or read, how good the Kenwood hybrids are, plus their price-points are certainly lower than most new gear, even new entry-level rigs. However, any rig 30+ years old requires attention, and most of us are looking through glasses of being hams for decades (52+ years in my case). For newbies, especially given the nature of the testing format today and lack of hands-on technical experience, it must be a formidable challenge.

Terry:

Recently over at QRZ a ham asked what I thought was a remarkable question.

He has a call like yours - letter, number, and only two letters after the number - a sign I have long taken to indicate immense practical knowledge and a vast amount of experience.

He was reading a manual on a Hallicrafters or something and it referred to a crystal calibrator.

He wanted to know what a crystal calibrator was.

I was flabbergasted, along the lines of a pilot for a major airline saying he had seen a new kind of airplane that had two wings, one on the top and one on the bottom.

One of my long term projects is building a couple of copies of a National XCU-109 crystal calibator for use on my Nationals that don't have one built in. Got all the parts, even cases, but just need to solder it all together, followed by what probably will be 6 months of troubleshooting (maybe the 2nd one will only take 3 months to make it work). But most people are not doing that kind of thing, and it is apparent that today many perfectly competent amateur radio operators regard what we once thought as "normal" to be a brave new and wonderous world.

You're not just a technical advisor; you're Obe Wan Kenobe!

Dan, thanks for your feedback.

When I transmit into the dummy load built into my MFJ-945c the SWR is close to 1:1 which is to be expected as the purely resistive load acts like a perfect antenna.

I guess my question is more about proper procedure when transmitting while performing the tuning process. Do you just find a frequency not in use on the dial (and allotted based on your license level)and start
saying '<Call Sign> Testing' while watching the SWR meter then correcting for an SWR close to 1:1?

Thanks,

John

Alan: Hoping not to get into this BUT.....

The issue here has NEVER been to discourage newbeeis or people without experience. The issue is that SOME people come here and EXPECT people to instantly be able to remotely diagnose their problems with a reply of "oh, just turn that screw halfway in". Well, it doesn't usually work that way, and the experienced folks are trying their best under extremely difficult conditions, which I don't need to relist again. The point is NOT that they are new to the hobby; Rather the point is that a few of them have rather realistic expectations as to what can be done and what it will take on THEIR part...not just a sit back and fix it for me world we have. I think the case of Barry? a few months back, who just got his license and joined the group showed great interaction...and great results.

After all, if we don't encourage "Newbees" in a few years there will only be "NOBEES"

John,
To answer your question more simply, "yes". I am sorry, I forgot that MFJ puts dummy loads in some of their tuners. I suspect that the dummy load will easily handle quick initial tuning of the rig.

One thing I always add, John, is I first thing ask "is the frequency in use" a couple of times. MANY times, you cannot hear both sides of a conversation and would be interferring if not. That is done by me on all modes, I'm old school, hi.
Enjoy the hobby,
Don, WB5HAK

Thanks for your input, Gordon.

My Great Uncle had been a ham for 55 years and I never even knew it until about 3 months ago. If I had known that I would have done my best to spend time with him learning more about the hobby and everything else, but I had always wanted to get into ham radio. A Southern Baptist Pastor's family does not have a whole lot of money available to get into fairly expensive hobbies, so growing up I dreamed about having some cool equipment when I received the Heathkit catalogs in the mail. Dreaming was all I could do back then, though, but I couldn't wait to look through every page.

After I worked pretty hard to have a little spending money, fast forward to a few weeks ago when I learned Uncle John was going into a nursing home and I had the chance to meet him at his shack to see what he had.

I knew very little, admittedly, about anything to do with ham radio, but over the years I knew nothing about restoring a 1949 Buick Special, a 1964 Plymouth Valiant convertible, and a 1967 Dodge Dart, either. Becoming President of a small company a few years ago in 3 months' time after not knowing anything about cultured marble, either, proved that I could do whatever I set my mind to.

So when I saw Uncle John's Yaesu FT-757GX and Kenwood TS-820 along with other equipment, that proved to be a challenge that I was up to. I had already begun studying for the Tech exam, and I knew this equipment was worth the money to me, plus I could help carry on some of Uncle John's legacy through his equipment.

I have learned a tremendous amount just reading these emails and have gained so much respect for the people that help me and many others here in the group. Yes, I've made mistakes, and I've ticked off one or two people along the way in one way or another.

That's not going to stop my quest for learning, my hope to improve in the coming weeks, and my desire to be great at ANYTHING that I do, much less ham radio. That's the drive the Lord put in me, and it won't stop.

So that's why I bought my TS-820. I've thoroughly enjoyed working with it and may keep it for a long time. Sorry if anybody thinks us newbies are pains to deal with - I've found a guy locally that helped me get mine transmitting that has been extremely helpful, but it took weeks to do so. This group continues to help solidify my learning, and I am very appreciative.

But do cut us a break when you can. I know, just like us, nobody was born knowing how to neutralize finals or how to align a rig when they were in kindergarten, so that says you learned from some patient people that showed you how when you needed it. Thanks to everybody that has helped me!

John,
Re-reading your last to me, I didn't fully answer the question. When transmitting to "tune the tuner" I use low level CW to do that. It's near impossible to tune the tuner with SSB anyway, so CW works well and you can turn the level down to 10 to 20W for initial tuning, then "touch it up" with 100w before going SSB. That make sense?? If you have no key to use, a simple spst switch will work fine with a cord and proper plug on the end.

Thanks for the feedback TJ!

Not knowing that status of my TS-520SE when it was given to me, I performed both the receive and transmit calibration procedures in the manual.

John,

My point is that using a simple dipole as a started is a better way than trying to learn to operate the radio and a multiband antenna system at the same time.

A 65ft dipole (40M) will also operate on 15M. The Kenwood hybrid can handle that just fine.

Then if you learn about TRAP antennas you can install a pair of 20M traps in your 40M dipole and operate 40M, 20M, and 15M without an antenna tuner.

Get operational at first with the simplest system. You can make a career of playing with antennas.

Bob, I started with a G5RV antenna because it seemed the best fit to cover all the bands I wanted to explore.

As I recall with a simple dipole, I could remove the Antenna Tuner from the equation if the antenna was the proper length for a single band, but I would be limited to the single band the antenna was tuned to.

To do antenna testing it needs to be done in CW mode.

Send "TEST callsign" them put the key down and make the measurements.

Dan, thanks for your feedback.

When I transmit into the dummy load built into my MFJ-945c the SWR is close to 1:1 which is to be expected as the purely resistive load acts like a perfect antenna.

I guess my question is more about proper procedure when transmitting while performing the tuning process. Do you just find a frequency not in use on the dial (and allotted based on your license level)and start
saying '<Call Sign> Testing' while watching the SWR meter then correcting for an SWR close to 1:1?

Thanks,

John

Alan,

If you want to work on this stuff yourself you need the proper test equipment and tools before you do anything else.

If you do not want to acquire the test equipment and tools don't mess with the radio. Find someone to do it for you.

Bob

Possibly quite simple - the older rigs are cheaper than even second-hand modern equipment. From my own experience, I was looking for an HF rig within my price range. Sure, I'd really have liked an FT-9000 (keep dreaming!) or even an FT1000 or FT2000. But splashing out £1500 on a new hobby was simply not an option. An older ham (now sadly SK) had a TS-530 for sale. A little googling returned highpoints such as fantastic audio.

What google DIDN'T show was the complexity of the set when troubleshooting. Neither did it really show the "complexity" of using it compared to a solid-state "power on and press the tune button". Neither did my good friend go into detail about that, hi hi. So no, I didn't know I needed probes, oscilloscopes, test meters and the odd sacrificial virgin. Glad I didn't know, might not have bought three damn fine rigs.

But, so what. Its good to learn, and so what if 'novices' are buying the older rigs - if 'experienced'* hams are not buying them, then who will?

*Based on my limited experience, even many M0/M1 (advanced/full/'experienced') licence holders would struggle troubleshooting a hybrid, as their experience is with solid state, and to be frank many study for the advanced exam and then have nothing to do with the more practical side of the hobby, beyond calculating antenna lengths - and I've been asked by M1's for help with this, me, a mere M6 licencee.

I really do not want to bash the newbies. But I would like to know why people are starting with complex radios like the Kenwood Hybrids?

My feeling is the problem started with the elimination of the Novice license. When a lot of us stated we built kits like the Heathkit DX-20, Dx-35, DX-40, or DX-60. These are all better starter radios than a complex solid state transceiver.

We combined these simple transmitters with low end communication receivers. Mostly Hallicrafters and Hammerlund. The Heathkit HR-10 is an excellent novice receiver.

This stuff is easier to get working than any of the Kenwood hybrids. But for the most part they are CW rigs. Actually CW/AM.

But they are far easier to get working than a old solid state rig.

The other thing is test equipment. The first thing you need is a decent VTVM and the manual. My preference is most any of the Heathkit VTVMs because they have the best manual. And don't hesitate to buy a good repro manual for your VTVM. If you are not able to repair and calibrate your VTVM you will not be able to repair a radio,

I would still like to know why people with no apparent experience are buying complex radios like the Kenwood hybrids.

Hi there

I think Alan has largely hit the nail on the head. I suspect many people looking for a reasonably priced rig as a starter are pointed at the hybrids by people who know and love the rigs and are thus per se generally older licensees who grew up with valve PAs and a degree of suck it and see operation. I'm not familiar with the detailed syllabus for the present exam's but I doubt that they require any great depth of understanding of valves generally or valve PA design. In those circumstances, taking on a hybrid rig, unless it's a known good one is probably not the best introduction to HF. Leaving aside all other considerations, as has been emphasised here, poking around inside (particularly the PA compartment) can be lethal if the precautions are not properly understood and implemented.

A working hybrid is not IMHO particularly complex to operate; the only difference from a modern solid state rig is the PA load and Tune routine which is well explained in a number of sources. I'd have thought it would be easier to "pop" a middle-aged solid state PA without the sophisticated protection offered by modern rigs than it is to wreck a valve one.

In my case, my reason for buying a TS530S and the associated line of extra units was that I returned to radio after nearly 20 years QRT and had no experience of menu-driven rigs. I decided to start with something I knew I could drive; a rig with a knob or button for every function and a valve PA which I knew how to manage. Two years later I've still got (and use) the hybrid but have also acquired a TS440SAT, again with everything accessible from the front panel and a Yaesu FT736(only because there's no equivalent Kenwood) for 6m, 2m and 70cms (not on there yet). I've still no desire to spend a lot of money on a menu-driven rig on which I'd probably understand maybe 50% of the options and then use 10% of those I understood! To my mind the one thing that might change my mind is shortage of space when the modern "shack in a small box" might be attractive.

I'm all in favour of showing patience with new licensees and I think that's what is done here. I can understand the occasional tetchiness when help is made difficult because clear diagnostic questions are not answered clearly. I think part of the frustration can often be that those of us who had to have a good grasp of basic electronics just to get a licence don't understand the degree to which that is not now required. Thinking about it I suppose it depends what is defined as basic electronics!!

Lastly, I sit here reading the patient thoughtful contributions of Terry and the other hybrid experts on this group with awe; I got my licence in the '60s as a teenager and later trained as a broadcast electronics engineer before moving onto the operational side of the business but could never aspire to the level of understanding of circuit operation and

trouble-shooting available to everyone from the experts on this group.

In the Beginning;
I started as a kid who knew nothing about radio but thought it would be fun.
In the middle:
 I learned a lot over the years and some times it took sweat and wasn't always easy.
Nearing the end:
Now people on these web sites hate me because I know how to tune up a tube transmitter and they can't. And they don't understand why.

Subject: Re: [TS-520_820_530_830] Re: Intermittent transmit problem on TS-520S

Hi
I have recently bought a ts830s because I like old radios. I have only had my licence for 20 months and come from a none technical background, and i find the idea that only people who have an understanding of how it works can enjoy these wonderful rigs abhorrent. It has been a very steep learning curve for me at the age of 64 the brain does not work so fast as when younger but I thought the idea of groups like this was to help people understand and keep these wonderful rigs alive. I will learn how to service and look after it because that is the nature of the hobby but please don't knock those who perhaps have less understanding than yourselves. We all had to start somewhere. Ok rant over does anyone know of someone in the UK who will be able to help with repairs or servicing if I get out of my depth please as most of the expertise seems to be in the States.
73 de Mike 2e0mcy (hopefully soon to be M0??? as just sat the exam)

From: John Haddleton
Topic: 44140 Message: 44173

Well said Alan......
I am a new licencee (ntermediate) and only took my Foundation 'Ticket' a couple of months ago... I run a complete Kenwood TS-830S Line up (See the pics on my QRZ page or on my Amateur Radio web site ... Links below!
The Kenwood out performs 90% of transceivers currently on the market (Check out Sherwood Engineerings league tables!) with 32 year old technology... I can A/B switch between the Kenwood Hybrid and my new Yaesu FT-950.... I get better transmitted Audio repoprts, and it receives weak stations in QRM/N just as well - plus it is a much more forgiving transceiver than a modern solid state rig.
Plate and Load is easy peasy, if a Newbie is shown how it works.... but as you say, Alan... The 'Mint' Kenwood in perfect condition cost me ?250 (375 Dollars), and the Yaesu 950 cost me ?1250 - a thousand pounds (1650 Dollars) more. So who are the idiots, and who have the brains ??
May I respectfully suggest, that in this case, this Newbie leaves a lot to be learned by older Amateurs.
Sorry - I forgot to tell you, I am an ex Radar and Radio Tech from the Royal Navy, and was a Radio Tech in the Royal Corps of Signals - now 77 years old, and just found time to start enjoying this great hobby !!
My web site is at http://2e0jjh.net
QRZ Page http://www.qrz.com/db/2E0JJH
Cheers Guys - Leaves with his Hard Hat on !!
John (2e0JJH

Subject: Re: [TS-520_820_530_830] Please help, Don't bash the Newbies

Bob

Possibly quite simple - the older rigs are cheaper than even second-hand modern equipment. From my own experience, I was looking for an HF rig within my price range. Sure, I'd really have liked an FT-9000 (keep dreaming!) or even an FT1000 or FT2000. But splashing out ?1500 on a new hobby was simply not an option. An older ham (now sadly SK) had a TS-530 for sale. A little googling returned highpoints such as fantastic audio.

What google DIDN'T show was the complexity of the set when troubleshooting. Neither did it really show the "complexity" of using it compared to a solid-state "power on and press the tune button". Neither did my good friend go into detail about that, hi hi. So no, I didn't know I needed probes, oscilloscopes, test meters and the odd sacrificial virgin. Glad I didn't know, might not have bought three damn fine rigs.

But, so what. Its good to learn, and so what if 'novices' are buying the older rigs - if 'experienced'* hams are not buying them, then who will?

*Based on my limited experience, even many M0/M1 (advanced/full/'experienced') licence holders would struggle troubleshooting a hybrid, as their experience is with solid state, and to be frank many study for the advanced exam and then have nothing to do with the more practical side of the hobby, beyond calculating antenna lengths - and I've been asked by M1's for help with this, me, a mere M6 licencee.

73's

Alan

Subject: Re: [TS-520_820_530_830] Please help, Don't bash the Newbies

I really do not want to bash the newbies. But I would like to know why people are starting with complex radios like the Kenwood Hybrids?

My feeling is the problem started with the elimination of the Novice license. When a lot of us stated we built kits like the Heathkit DX-20, Dx-35, DX-40, or DX-60. These are all better starter radios than a complex solid state transceiver.

We combined these simple transmitters with low end communication receivers. Mostly Hallicrafters and Hammerlund. The Heathkit HR-10 is an excellent novice receiver.

This stuff is easier to get working than any of the Kenwood hybrids. But for the most part they are CW rigs. Actually CW/AM.

But they are far easier to get working than a old solid state rig.

The other thing is test equipment. The first thing you need is a decent VTVM and the manual. My preference is most any of the Heathkit VTVMs because they have the best manual. And don't hesitate to buy a good repro manual for your VTVM. If you are not able to repair and calibrate your VTVM you will not be able to repair a radio,

I would still like to know why people with no apparent experience are buying complex radios like the Kenwood hybrids.

I just bought a '60 Lincoln hardtop convertible, can someone tell me how to drive on the freeway with it and get the top down ??
Just too broad a question.
 Do you have the manuals for this equipment? read and then come back with a more specific question if you don't understand some part of the instructions in the books.

Subject: [TS-520_820_530_830] TS-520SE Tuneup Procedure

I have a TS-520SE connected to a MFJ-945c antenna tuner. The MFJ-945c is then connected to an outdoor MFJ G5RV antenna strung between trees in my backyard. I want to transmit on 40m SSB. Can someone describe the antenna tuner procedure I should follow before transmitting?

Thanks!

44175. Re: TS-820S Display problem even after working on DG-1

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-21 17:52:15 UTC
From: coyoteinventor@ymail.com
Topic: 43702 Message: 44175

I went ahead and re-soldered all front and back connections on the DG-1 board (the one that has all the ICs), and now the display seems to be working well (not jumping around and turning off) on most bands (29 and 29.5 keep jumping around, but only the last 2 digits now). So, overall I'm happy with the outcome.

There is one problem, however, where I am looking for some feedback. The display seems to dim from bright to barely visible, back and forth, as it wishes (even when nothing is being touched). Is this a bad ground? I just want to see if someone had a suggestion on which direction to proceed.

But, like I said, I'm pretty happy the way it is now, even if I have to deal with a very dark display sometimes; At least I can see what frequency I'm on now! ;-)

Thanks again to all those of you that contribute to this yahoo group; definitely an invaluable resource for these old radios!

Before you take the cover off, just verify that
the plug is still inserted in the VFO plug on the
rear of the radio. While doing that, go ahead and
pull it out and reseat it several times just in case it's become corroded.

Never know when it could be the simplest of things.

Tim, Maybe I misinterpreted how you described your procedure, it was somewhat vague in details.
 all I can say is I used my TS520 for almost 40 years, ran it side by side with other older and newer rigs, Repaired it when faults developed, Put it on the bench at my shop and checked it with professional communication monitors to see how it performed, and know how it works.

That's OK if you STAY AWAY from band edges since you are almost 1K off freq.

@John: I did state I was in the TUN
position (see 00:15-00:20), but
otherwise your procedure matches the manual. The TUN mode also corresponds
to the CW mark, but instead of the 700Hz offset to the lower side only, you
can use the valley null to zero. I am not saying this is the proper way,
it's just the way I was shown, and it works great for me for a reason.

Topic: 44178 Message: 44178

About three years ago I bought my TS-520. Why did I buy a TS-520?

I own several other good boatanchors. I have a set of Heathkit Benton Harbor S-Line twins. They work well.

I also have a set of Drake 4 Line twins. The receiver is actually more sensative the the SB-301.

Both of these are good sets.

But I did not own a HH tranceiver. Someone I respect told be about the TS-520. The TS-520 uses the same conversion scheme as the Heath S-Line does.

He told me how nice the VFO on the TS-520 was. I found out how correct he was. It is a very nice VFO. The Heathkit is a bit rough but mostly because of age.

So far I have only used my TS-520 as a receiver. It compares favorably to the SB-301. A few weeks ago I put a CW filter in it. It works as expected.

In addition to the TS-520 I have SP-520(speaker), a VFO-520, an AT-200, and a SM-220. All of this stuff working.

The problem is I don't hear much here in Seattle except on contest days. I use the contest days to test my toys. The last two contests were disasters. Not because of my radios but because of the way contests operate these days.

When Heathkit converted the SB line to solid state they were developing a tranceiver similar to the TS-520. It was to be the SB-103. But it took too long to develop and was dropped in favor of the fully solid state SB-104.

The only solid stte HF stuff I have is the TS-520 and a Kenwood R-2000. I can hear more on my TS-520 than I can on the R-2000. Need to try working on it one of these days.

Robert:

I saw it as well and was really surprised. I dont think you can tell anything by the call sign any more. Maybe at one time but not now. If he was my vintage and doesnt know what a Xtal Calibrator is then he has slipped a cog or two.

Yes I got my ticket under the old method and it was not easy but I think we were better prepared. FCC made it scary process by how they outfitted their field offices (nice hard upright wooden chairs) and staffed them (stern faced bank examiner types). I took all my exams in Chicago.

There is no substitution for 50 years of experience. However everyones experience is different. I chose to focus on the building, repairing, testing side and not so much the operating side all though hearing my call come back in CW on 40 meters that first time with my rock bound transmitter is still a very fond memory. Today I am not a very good operator. I am also still learning and sometimes even with some very fundamental things the light bulb all of the sudden just comes on after all these years.

How many of us can explain the voltage and current phase relationships in a Pi-network? What is the effect on the PA by tuning the tank capacitor to the inductive side of resonance? Why does a heterodyne oscillator coil have a fast and slow dB/octave side to it? All of these things take time to grasp. Almost all of us who have done coil pack alignment have noticed that coils have a fast and slow side. How many questioned why or just knew intuitively why and how many hit the books trying to figure it out? It takes a different way of thinking. Not a better or more legitimate or more value added way just different approach to the hobby.

We are blessed today with these computers and I would never think to go on any forum and ask what a Crystal Calibrator is. Only after a Google search and still not understanding how to use it or how to calibrate it would I ask such a question.

Have fun with your Xtal Calibrator project. Not unusual for most of my projects not to work first time. Part of the fun is pinching a coil here or spreading the turns here and watch it come alive.

I tuned my DX20 into a 100 W light bulb to make sure it had some output. Orange glow was about right. I also wrapped a few turns of my end fed wire antenna around a burned out fluorescent lamp and lit it up when I keyed. More of a curiosity than anything useful :D

I have a smart phone. I don't need a DVM, oscilloscope, signal injector, tube tester, or any other equipment to use it or maintain it. At the very worst, if it can't be repaired I'll replace it.

The idea that a ham radio operator in this day and age needs to be an electrical technician is as archaic as thinking Morse Code is still relevant for more than 2 or 3 percent of communications --or that you could be a shade tree mechanic for any car built in the last 10 years.

It's this outmoded way of thinking that has hobbled ham radio for the last 30 years and nearly brought about its death. Maybe if we can shake this 1950's mindset maybe we can start rejuvenating the hobby.

Maybe it would be better to figure out why amateur radio repair companies seem to be too few and too far between and why every d*mn radio I need fixed seems to cost $300+ no matter what the problem is. ("Well, you know it takes me about an hour to unpack and repack the radio and that's my time too." Oh give me a frackin' break!)

Only game in town in the late 50s early 60s. Also used on test benches for years. QST ran articles on resistance vs temperature vs time. Almost unity power factor. Dont want to get into it here as will be much disagreement about using one that will drag on forever. Only real problem is that they are pretty good radiators. In a pinch I would not hesitate to use one to test a hybrid if it was all I had. Pi-network will tune just fine into them.

BINGO! Give that man five silver pennies!

Price for new gear has been driven through the ceiling, and all of the marketing emphasis on "Just throw it away and buy a whole new one" kind of 'troubleshooting' and 'maintenance' has made this a whole generation of throw-away semi-educated Hams. All to the detriment of the hobby, in my opinion.

We need MORE people like Terry and Mike and the bunch here, who -care- that those of us less-informed about these boxes figure them out, and not just sit there, drooling, and twiddle dials.

>Sure, I'd really have liked an FT-9000 (keep
> dreaming!) or even an FT1000 or FT2000.

There's where we differ immediately. I went actively searching for a hybrid rig, because it CAN be repaired.

The only thing I'd like in a "modern" rig would be one that would fit in a small satchel and be completely portable for when I go on the road (antenna of course, to be arranged as and can).

> What google DIDN'T show was the complexity of the set when
> troubleshooting. Neither did it really show the "complexity"

I think these are immensely LESS complex than the digital stuff. You can look at a lot of it and tell if there is something (catastrophic at the very least) which has failed. You don't have to just scratch your head and stare at a black box, with no way to gain any comprehension fo what is going on inside.

WE are immensely fortunate, for we have manuals and schematics, and good people who can point to those documents and tell us what and where to look for the problems (AND WHY TO LOOK FOR IT THERE!!), and even with shortages of the odd component, we can then FIX THE ONE THING THAT IS REALLY WRONG. In contrast to tossing in the binnacle a lot of things which are not even broken, just to get to the one tiny bit that is.

So I feel that the Kenwood and other hybrid owners are one up on the "This is NEW and therefore must be better than anything at all OLD!" crowd.

We only have to avoid the other half of that paired set of fallacies, the mind-set that insists that "This is OLD and therefore it MUST be the best thing there is; no NEW thing can be even slightly useful in comparison."

I try to take the best of both halves, and put them together when it is possible. I just scored a kit Micro908 (almost entirely surface-mount soldering, oh joy, what fun for these old eyes and hands, huh?) antenna analyzer that will finally make the loss of my grid dipper a thing to be forgotten.

And I plan on using this modern and very much digital gadget, especially some of the signal injection functions it can have, quite HEAVILY in tuning and troubleshooting my poor old 520SE.

Tubes, meet young Billy Digital-IC, he's the new kid on the bench. Digital-IC, this right here is Mr. B-PLUS. Watch out for him, he's an old dog and might BITE YOU. Hard.

No one has said that at all. Where and when did you hear that on this forum?

People who buy these hybrids come here asking for help when their newly acquired 30 to 40 year old eBay treasure doesnt work. We dont seek them out. With their backgrounds we could say no user serviceable parts inside and tell them to move along. Those interested in learning will be helped.

If you own one of these rigs and intend to maintain it or repair it by yourself you have no choice but to move to the tech side of this hobby. There is room for all including the appliance operator as there always has been. It is natural that appliance operators are looked at with distain. This started as a technical hobby. Nothing wrong with having elite clubs with high standards for admission. What is wrong is the dumbing down of just about everything for dollars.

You can chose to just drive your car today and take it to the dealer when it doesnt work or if so inclined you can buy tools and diagnostic test equipment and go to a forum and start learning all about the ECM and how a open loop vs a closed loop fuel injection system works. It will be as daunting a task as these new Kenwood Hybrid owners are taking on if they so choose.

I smell sour grapes. Suspect you would have had a real fun time during incentive licensing.

Once you have the proper tools, test equipment, and manuals restoring old radios can be more fun than operating new radios.

My feeling is we need regional groups that can get together for repairing this stuff. It's a PITA to ship it to someone for service.

Not all the common problems can be handled by a newbie. Sometimes they cannot explain the problem accurately.

If you want restore one to original factory specs like Terry and some others do it requires good test equipment and the knowledge of how to use it.

If you just want to get one to a useable operational state it requires less.

> Sorry if anybody thinks us newbies
> are pains to deal with - I've found a guy locally that helped me get

"Pains"? Why sure you're all pains, and so are we, to you and to each other. Which is as it should be. No pain, no transmit, maybe?

But any growing is accompanied by a bit of pain, and anybody who cannot stand that kind of pain needs to just stay quiet and let those who can go ahead and grow some.

That's my opinion, and I'm sticking to it.

And here's another opinion of mine: The absolute, utter, MOST fun you can possibly have in this hobby is when some "pain" calls you their

"ELMER."

Particularly one who is about fourteen years old, dresses "weird" and who you can only understand about half of what they're saying. In other words, they're YOU when you were that age.

I mentioned that the only thing I would find useful about a very modern rig would be one that was completely portable and very forgiving on the antenna end of things. This is because the "on the road" function for me would be regularly taking it to my wife's school, and setting it up to teach any of the kids there about radios. ANY of them, of ANY age, from 6 to 18 (plus the staff and educators if they show an interest).

Once I finish with getting my 520 on the air so I have something to use for myself, that's -precisely- what my next piece of (non-test-bench!) equipment is going to be. Something battery-powered, easily-portable, and broad-banded. Yaesu has some like that, also Kenwood (which brand I would prefer), as well as others of course.

And one of my internet contacts down-under in Oz has pointed me at a 'kit' radio which sells for about AUS $250 or so there. It's called a "G-11" and the outfit making them is "Genesis Radio." They have a web site,

http://www.genesisradio.com.au/

which has links to download all the manuals and the bits of software for this completely-computer-controlled monster. DON'T skip the dot A U at the end of the URL there. The dot-com is just another punkish kids' FM radio station web site.

Ten watts out, enough to drive an amp to get a hundred. And a kit amp to match it. Plus other odds and ends, looks like a good bunch of folks

to check out if you want a full-out software-driven radio to play with along with your hybrids. I won't be using one, sadly. Looks to be all WINDOWS junk, and I don't use that piece of garbage. (Not after twenty-plus years cleaning up the mess Redmond makes of a computer. NOBODY needs that much "job security.") I run Linux of one sort or another, and NOTHING from the M$ crew. They don't list any sort of Linux compatible stuff out front where it's easy to spor.

(Plus, I will bet their solid-state all-digital "WinBlows" gadget doesn't SOUND as good as the Kenwood tube boxen.)

I forgot to mention that no one who just wants to enjoy the operating side of this hobby (rag chewing, chasing dx, contesting etc) with their "new" KW hybrid has ever been told they are not welcome here. Anyone having trouble tuning and loading the radio or worried about why the S-meter pegs during initial power on is given the guidance they need.

However, regards tuning and loading the radio they will be advised by me and some others that it is in their best interest to begin learning what is on the end of those knobs that they are turning in a sequence that is somewhat of a mystery at this point and what and how they do it. The knowledge of parallel resonance, tank circuits, pi-networks and how and what they do is especially helpful when turning the knobs does not produce the expected and desired results. Then that may lead us to antenna systems. Another technical topic that abounds with misunderstanding, myths and magic.

Topic: 44140 Message: 44191

I was once the new kid on the block, and probably a big pain in the rear with a million questions. My first rig was a FT-101E, and it worked great, but I wanted to know how to fix it if it stopped working properly.
I am like a lot of the Old men around here that started with an interestt in electronics and found ourselves deeply interested in radio for one reason or another. I never studied for the Novice license, ans I should have cause I was nervous ad hell when it came time, but I nailed i and moved on to my Tech license that was where I wanted to be fr the time being, and 13 or so more years.

I thought I knew a lot already about electronics and radio, but over the 16 yrs I have been licensed now, I have learned so much more, and am now a General class license holder.

I am sure I still dont know half as much as I think I do, but I keep trying. I read a chapter or so of the ARRL handbooks. I have a few of them going back to 1981 for me, and that is fine. I started reading them in as a very young kid, and dint understand most of the words let alone what they meant but I kept at it. I learned how to make antennas real fast and used that for every thing I could touch. Not knowing the rules really I didnt pay attention to what was allowed or not, and modified cordless phones with true Base antennas for 49MHz, CB radios(11m). I learned how to modify stereo antenas to get what I wanted out of them. My first 2 meter antenna is the $20 special modified TV antenna, and it worked so well, I was convinced that is all I ever wanted to do. Little did I know I was learning a lot.

I did not have an elmer, and did not know anyone into electronics or radio at any level. I screwed around with the CB into my mid 20's and then said screw this, I am tired of running illegal power in excess of a couple thousand watts with an Omni antenna at 90 feet above ground level. no modified radios though. I was heard everywhere. One day I moved into a new neighborhood and found my neighbor was using the FT-101E as his CB rig with a 3K palomar RF amp, so I bought it from him for a few hundred dollars, and the rest is history, I still use the cb, I lost the Yaesu FT-101E to theft, got it back many years later to have it stolen again a year later out of the RV.

Anyways this Hobby of Amateur radio is technically not a hobby, as defined by the FCC in its purpose of use. It is a Scientific research and developement arena, where experimenting with radios amps, antennas, coax, and many other things are expected for the growth of this hobby. It has never been in real threat of going away other then by rule making and frequency grabs. Our numbers now are higher then ever before in the history of amateur radio.
The problem lately that I see is a lot of newbies that have no desire to

learn anything, they want to plug it in and start talking and have no clue what they are doing or how to ensure frequency stability and tests. most have no clue how to check audio bandwidth being used a VOM, or DVOM wont tell you that, but an O-scope will.
Many new comers have simply said they only became licensed for the world end and TSHTF incidents. Fear mongering seems to be a good marketing ploy never used but some how a bunch of newbies think it is the only way to go. and still think that because they have a Handheld dual band they dont need a mobile rig or they think that the little HT will be just fine in a NYC on the 3 millionth floor of some building or another, never realizing the 2 meter signals dont penetrate walls to well, but use UHF and things change a lot.
Appliance users is exactly what the hobby has turned into now days.
So here is my suggestion to the newbies, quit bitching about us Old timers, and respect the fact that we can keep your radio in working order as well , while you have no clue what the TV seep tube is doing in a radio! Lighten up, you are not going to change this hobby simply because you are younger and think you are smarter. If you wher that smart you wouldnt be asking how to install the battery on the FT-897D or how to use the notch filters.

Oh by the way, 16 yrs in the hobby, and I still claim to be new to what I do, because I find the desire to keep learning and stepping into areas, I honestly have no clue what I am doing other then following directions on building a digital interface for my TM-V7A to the laptop because the screen has gonedark for ever now, unless I use on computer with some CAT controls. which note for you new comers is an excellent way to keep an older rig that otherwise works perfectly in use.

just like I dont understand the lyrics I hear on the radio as I call it jungle music I hear others calling it wrap, apparently speaking in rhyme is the new way to make noise, and yet not many have the ability to play any instrument and now days even the mic does a lot of the effects and clean up of a person who cant sing, Nikki Manaje comes to mind, right next to Justin Beiber!

Give us old guys a break and be happy you have someone to turn to at the end of the day to help fix your rig after you got stupid with the golden screwdriver some of you may have learned from the 11 meter band. We respect your ability to communicate, and the value you are to the hobby, not counting a numbers game of population in the Amateur radio service. Numbers help save things, but use of frequencies helps more, and so does experimenting with something related. I got in whe SDR was just developing, I still dont understand it, or D-star which I think is useless, I can use VIP with my vonage if I need to talk to England so bad.

Oh never mind some of you are hell bent on your way and that is it, but once you have been around for a bit you will learn much more then how to push buttons, you will finaly understand what that button does, in the mean time, keep asking questions until you understand the answer!

I have a smart phone. I don't need a DVM, oscilloscope, signal injector, tube tester, or any other equipment to use it or maintain it. At the very worst, if it can't be repaired I'll replace it.

The idea that a ham radio operator in this day and age needs to be an electrical technician is as archaic as thinking Morse Code is still relevant for more than 2 or 3 percent of communications --

It's "phone" or "telephone" --but that is the attitude I've experienced from some Yahoo group members. I have the same authority to define what amateur radio should be in the 21st century as you do for the 19th. My definition keeps the hobby alive.

Hang a fluorescent tube at each end of your dipole or inverted vee and scare the heck out of your neighbors at night.

Don't own a Cantenna but have lots of light bulbs that I can use for a visual dummy load. Not a bad modulation indicator either. For precision dummy measurements, I have a homemade dummy load/wattmeter consisting for 4 American Resistor Co. Globar 200 ohm non-inductive resistors (each resistor roughly 20 inches long by 1 inch diameter).

I had a NE-51 hanging from my antenna in 1957!

And I was asked about the blinking light!

Hang a fluorescent tube at each end of your dipole or inverted vee and
scare the heck out of your neighbors at night.

Don't own a Cantenna but have lots of light bulbs that I can use for a
visual dummy load. Not a bad modulation indicator either. For precision
dummy measurements, I have a homemade dummy load/wattmeter consisting for
4 American Resistor Co. Globar 200 ohm non-inductive resistors (each
resistor roughly 20 inches long by 1 inch diameter).

I had a couple of “ Tandy “ bulb dummy loads for my CB back in the 70’s. Only problem was if you accidently swung over to SSB and forgot to reconnect your antenna.... (they were 5 watt)

That’s why I had a couple of them <grin>

Cheers,

Rob VK3BRS

Didn't hear it, read it.

"It is natural that appliance operators are looked at with disdain."

Now there's a nice juicy statement for the list. Does everyone agree with that? Do the people who make buggy whips look down on automobile drivers?

"You can chose to just drive your car today and take it to the dealer when it doesn't work or if so inclined you can buy tools and diagnostic test equipment and go to a forum and start learning all about the ECM and how a open loop vs a closed loop fuel injection system works."

That's inordinately expensive and counter productive. My Corvette had (I think) 12 computers connected serially. If something happened to one, the rest down the line reported errors whether there were any or not. But they all had to be diagnosed --just in case. Great work of intelligence that was. The dealer service teams are already trained to do that job. I could get a forge and cast my own yellow wheels too but I think not.

The only sour grapes here is that the FCC/ARRL/ and radio manufacturers botched the whole thing so badly in the early '80's to the result that I let my newly won Novice license die off and didn't go near amateur radio again until last year --now that my eyes aren't as good, my hands only have limited dexterity, and I'm in pain to some degree or other 24/7 thanks to diabetic nerve disease.

I knew 5wpm when I got my license. Don't know any Morse now and won't learn Morse Code or any other useless aspect of ham radio at this time. It's the dead and dying past. If the Zombie Revolution comes to pass and spark is the only way to get a signal from point A to point B through the ZRM, I'll reconsider. ;-)

>
> If you own one of these rigs and intend to maintain it or repair it by yourself you have no choice but to move to the tech side of this hobby. There is room for all including the appliance operator as there always has been. It is natural that appliance operators are looked at with distain. This started as a technical hobby. Nothing wrong with having elite clubs with high standards for admission. What is wrong is the dumbing down of just about everything for dollars.

>
> You can chose to just drive your car today and take it to the dealer when it doesnt work or if so inclined you can buy tools and diagnostic test equipment and go to a forum and start learning all about the ECM and how a open loop vs a closed loop fuel injection system works. It will be as daunting a task as these new Kenwood Hybrid owners are taking on if they so choose.

Anyone having trouble tuning and loading the radio or worried about why the S-meter pegs during initial power on is given the guidance they need.
>
> However, regards tuning and loading the radio they will be advised by me and some others that it is in their best interest to begin learning what is on the end of those knobs that they are turning in a sequence that is somewhat of a mystery at this point and what and how they do it. The knowledge of parallel resonance, tank circuits, pi-networks and how and what they do is especially helpful when turning the knobs does not produce the expected and desired results. Then that may lead us to antenna systems. Another technical topic that abounds with misunderstanding, myths and magic.

As for the sound I have static noise also I can turn on moni and key the mic an speak an it works fine . The vfo digital display barley lights up then fades out Hope this helps. Thanks Ron Kk4 pwf

Maybe not a dim bulb, but I did have a QSO with an aquaintence who lived a mile away when I was connected to a HeathKit Cantenna on 10M SSB once.
I was tinkering with an audio compressor I built, hooked to my TS520, and got a call on the air from a guy who heard me at S5 a mile away.!

Ron:

I think you mean the IF board and if so VR-2 trim pot is the span adjustment for the S-meter. You use it to cal the S-meter by injecting 50uv or -73dBm 14.2mhz into the SO-239 and set meter to S9. The service manual has the steps to set zero and threshold before adjusting VR-2.

If VR-2 is broken it should not shut down your receiver. If the meter FET Q4 is shorted then you will have no receive because the AGC bus will be pulled down. This normally would cause the S-meter to peg full scale. Since you have a bad VR-2 then you would not be able to see the pegged S-meter.

1. What does the Marker signal (25khz xtal calibrator)do?

2. Do you have a high Z meter (VTVM or FET DMM) that you can use to measure the AGC bus voltage? You can measure it at IF board Conn IF-3 Pin 11. Will be something less than 3.0vdc with RF gain full CW.

3. Have you tried pulling and cleaning the Aux Relay contacts?

4. If you have no or very low AGC bus voltage and cleaning Aux relay contacts does not restore it go back to Conn IF-3 Pin 8 and measure RF-1 voltage it should be approx 3.5vdc.

OK your RF-1 is a little low and we can adjust that. Your meter is pulling down the agc bus slightly but with 2.55vdc on it the RF and IF amps mosfets are turned on so this is not the problem.

Go to AF-AVR board and connect voltmeter to Conn AF-2 Pin 6 and adjust trimmer pot VR-1 for 3.5vdc. I think you already reported that you had good 9vdc. Is that correct?

I am assuming the receiver is dead on all bands. Is that correct?

Did you check 8/9 jumper as previously directed and exercise the plug?

Assuming that the Marker is working you know you can rule out bad TR relay contact, bad xvtr switch, and bad RF attenuator switch.

Do you have a RF signal generator?

Do you have a RF probe for your VTVM/DMM? Need to be able to measure VCO and VFO signals.

Hi Robert:

I missed that. When he said VR-2 was broken I didnt see anyone responded to that. I was headed to VCO on RF board but wanted to make sure he had good AGC bus. The PLL may be unlocking and he will need a rf probe/vtvm or O-scope and can quickly see if he has VCO signal at RIF mixer.

If you and/or Joe want to run from here go right ahead. I have plenty to do. I think he is getting close to needing more than a DMM.

I almost always start by checking and setting 9vdc and RF-1.

When I find AGC bus voltage missing or VCO missing sometimes I will stop and provide it from bench supply or sig gen just to see if rig comes alive and then I move on to fix why it is missing. At that point you know the rig is capable of receiving and not multiple problems.

Hi All

Does anyone know of a decent Technician for my ts 830s resident in the uk. I have recently acquired the rig and on tuning into a dummy load I get no meter reading when trying to dip the plate and on switching the meter to rf to peak it get no meter reading also. Everything else seem to be as it should and the receiver is very good but as yet I don't have the confidence in my ability to delve inside in case I do more harm than good. Any help would be appreciated.

Bought a 830S recently & started benching it...
During tune-up I could get the 100 watts of CW into my Bird dummy load but at near 300 ma IP...
Everything seemed normal except the high IP...
Pulled the final board & took a peak at the cathode resistors, all 4 were cracked & swelled as I suspected...
My Fluke was measured 8 ohms, not the 5 ohms...
Replaced the final board & all is well, full 100 watts with 225 ma IP..

Bob,

  Nice feeling when the repair costs a few cents(for the resistors) instead of a few hundred!
But hey...you probably got a few spare final boards sitting around doing nothing anway...hihi

The closest one I can spot on Terry's list (the list which he just sent around) is:

KC9INK, Walley, Indianapolis, IN,
Does local repair work only, E Mail wallydoc@...
Phone 317 823 9380
(Also TS - 940 repair)

From that it looks like you would have to drive it up to him since it says "local only." Or possibly drive up and get it once it's done after mailing it. Considering what they weigh the cost of the drive and the cost of postage are likely close enough to the same to make the road trip the better option.

Hi Mike

I don't know any specialist hybrid fixers in the UK but it might be worth contacting your local clubs as many have an old hand who might look over the rig for you. Distances are so much shorter in the UK! Before you delve in to the case, I'm sure there will be helpful advice offered by the excellent engineers on this list which will narrow down the problem area. I'm not one of them but my first question might be whether you are seeing any meter indication in the ALC position with the rig in "tune" and "send" when trying to peak with the drive control.

A good 1st question. Assuming answer is yes then make sure the screen grid switch on back of rig hasnt been bumped to the off position. Will get good ALC indication in Tune mode with it off, but no Ip indication in Tune or CW as the screen grid voltage has been switched off and -C (approx -100vdc) applied to the screens cutting off the tubes. This feature is there primarily so you can cold neutralize the radio when installing new final tubes. Not uncommon for the switch to get inadvertently moved when handling the rig.

Hi Guy
Thanks for that and yes all readings are as you would expect til you get to the dipping/peaking of the plate it is only then that I get no meter reading. I have followed the procedures exactly as described in the manual.

> A good 1st question. Assuming answer is yes then make sure the screen grid switch on back of rig hasnt been bumped to the off position. Will get good ALC indication in Tune mode with it off, but no Ip indication in Tune or CW as the screen grid voltage has been switched off and -C (approx -100vdc) applied to the screens cutting off the tubes. This feature is there primarily so you can cold neutralize the radio when installing new final tubes. Not uncommon for the switch to get inadvertently moved when handling the rig.

Mike,

Have you adjusted the RF pot at the rear of the radio or tried moving the carrier pot on front panel, just incase that have a little corrosion on contacts?

Hi Guy
Thanks for that and yes all readings are as you would expect til you get to the dipping/peaking of the plate it is only then that I get no meter reading. I have followed the procedures exactly as described in the manual.

Did you set the resting plate current to 60ma before attempting to load the rig?

After adjusting the Drive control for peak in ALC indication in Tune mode are you then flipping back to REC and switching the meter switch to the IP position. Then flip to Send and adjust the Plate Tune control for a dip in plate current (Ip). Must leave the Car Level pot where you had it when you were peaking the drive. OK to run Car Level pot full CW if in doubt. Is this the point where you see no Ip indication?

If so can try to load in CW mode instead of in Tune. You will be making initial plate dip with full Screen grid voltage so must be done quickly. If plate current pegs dont leave it there.

To help prevent pegged plate current pre-position the Plate Tune control close to the white mark on the arc for band you are loading on. This gets it close to proper place (tank to resonance) so current should not peg or be too high when you first flip to Send.

Now flip to Send and adjust the Plate tune control for the minimum plate current ie dip. Flip back to Rec. If this works and you are comfortable can now just go ahead and load to full output by using the RF detector position as described in the 830 instructions or if you have external wattmeter use it to load to approx 100 watts out and check Ip to make sure not exceeding 265ma. If Ip is above this level just turn Car Level control down. Most of us find we can load to approx 100 watts out into 50 ohm dummy load at approx 225ma or slightly more.

If you can get plate current dip and load the rig in CW mode you have bad divider resistors R15/R16 56K ohm in Tune mode that produces lower Screen grid voltage. Common for one or both of these resistors to fail. Come back for direction on how to replace if so inclined.

Tom,

  There is a list of repair guys in the "files" section...but, I have used Mike Alexander/n0bxe of "Affordable Radio Repair" several times.
He is in Colorado...does fantastic work...and is inexpensive...about $35/hr and usually fast turn-around time. Search for him and read the info he presents.

Ron,

The following document contains all of the repair and parts locations for the Hybrids. The closest might be Jeff, WA8SAJ in Cleveland, or KC9INK in Indianapolis, IN.

http://wb4hfn.com/KENWOOD/Kenwood-Articles.htm

Good luck.
Mark

44238. Jan 6293 tubes

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-23 21:26:51 UTC
From: Joseph Stiles
Topic: 44238 Message: 44238

Greetings,

I have here a "rescue radio." It was destined for the dreaded "CB hack," but it is now safe and sound.
Upon inspecting it, I found that the final amp tubes were marked "Jan 6293." Research shows that they are
in the "6146" family..most closely the "A's." Usage was stated as being used in "burst" RF output, up 1 KW.
Has anyone seen or, used these before in the KW hybrids or, any other ham gear?

Tom,

There is a list of repair guys in the "files" section...but, I have used
Mike Alexander/n0bxe of "Affordable Radio Repair" several times.
He is in Colorado...does fantastic work...and is inexpensive...about
$35/hr and usually fast turn-around time. Search for him and read the info he
presents.

Hello Joe and others on the Reflector:

I'm currently running a pair of 6293's in my TS-830S. They're performing FB with rated power output. I strongly suggest these tubes as they're extremely heavy duty. They were originally designed for radar pulse service.

Regards,
Steve, N6HK

From: roberteleazer@rocketmail.com
Topic: 44238 Message: 44243

Here is a quote right out of an article I found online a while back on the 6146 family of tubes:

"There is another 6146 family tube that is "superior" for operation at least through 10 meters. That is the 6293. This tube was designed for "pulse" service and is rated at 1-Kilowatt pulse power input. The primary difference between these and the "normal" 6146 is that the plate is much "heavier" in its construction. Back in the late 1950s and early 1960s we would almost "kill" to get our hands on a pair of these for our DX-100s, etc. The 6293 outlasts the 6146 in "normal" service by at least 5 times and often more than 10 times the life of the tube. These tubes "show up" at hamfests, swap meets, etc., from time-to-time. If you see some of these, definitely "glomp" onto them!

The 12-volt equivalent of the 6146 is the 6883, the equivalent of the 6146A is the 6883A, and the 6146B is the 6883B. Now, there are the tubes that were manufactured for FM commercial service. These series go as follows: 6883, 6883A / 8032, 6883B / 8032A / 8552. Again most of these are "cross branded" with all of the tube numbers that are equivalent."

So it sounds like you have a real find in those 6293's, Joe.

As for me, I have some 6883's and plan to try them out in a TS-520 I am repairing. I'll have to rewire the filament string to accomodate them, but that is minor compared to the rewiring required to repair that radio.

I also have a couple of the 24 volt filament version of the 6146, the 6159. I think I paid $10 for the pair, including shipping. Don't yet know what I'll use them for.

Robert

My 830's been on the shelf for 15 years and I fired it up today to check it out. Here's as far as I got:
* Verified bias is 60ma
* Tuned for ALC, LOAD full CCW, CAR has to be set at 9 oclock to stay in the ALC range
* Tuned to dip plate current, meter reads zero all the time.
* SG switch in back is ON.

Any thoughts on how to bring her back to life?

A thought, but DON'T do it, from the early days of the personal computer. Amiga computers, to be specific. Manufacturer's bulletin came in, problems in a whole batch of their newest claim to fame. The solution (PLEASE DON'T DO IT!!):

Lift the box a measured six inches off of a firm desk or table surface.

Let go.

(Seems that it seated some chips that weren't quite in their sockets. Valid fix, it worked a treat.)

Instead, first I'd check the jumper plug on the back and make sure it's in there good and snug, maybe pull it and replace it a couple of times. Then if it still doesn't play nice, I think I'd open the case and inspect the molex plugs, maybe pull them gently (straight up, isn't it Terry?) and see if there is not some corrosion on there that exercising them didn't break off and polish. Gently. No need to make a small problem into a big one.

Seating the tubes in their sockets is next, watch for the high voltage inside the PA cage and all that.

That's where I would start. If the folks here who have done this longer than me have a better idea, go with what they say instead. But I'd check for corroded or oxidized connectors first.

Then I'd check to see if the tubes had gotten gassy.

Good luck with it.

Whoops. Sorry. 830. I thought it said 530. Never mind the jumper.
Wrong model.

If you're up to checking the board connectors without zapping yourself
on the HV section, I'd at least inspect them for any signs of corrosion.
900vdc HV reading is spot on, so the resistors and caps in the PA cage
are probably OK, likewise the choke in there. Best stay out of the PA
section until and if it becomes necessary.

Do you have the service manual downloaded for your rig? Check for the
proper bias voltages on the test points it shows. I don't have that
radio, never even seen inside of one, so I can't be specific here.
(There are various values, the 9vdc for most of the boards with IC's and
transistors (VCO, VFO, Balanced Mixer section, all of that.)

If you've got the high voltages, and the bias voltage levels from the
power supply/rectifier board, and none of the connectors is corroeded,
cracked, or lifted off the board, then we're at the point I drop out of
here and learn from the experts while they talk you through finding what
went south during the last 15 years.

I could download the schematics and the service manual for your type
box, and try to fake it, but I'm not that big a fool. And I do NOT want
you to make a very-likely small problem worse with me bumbling around
all thumb-fingered and foolish. Check visually for anything that looks
as if it might be corroded.

Dull solder, whitish powdery stuff on a molex connector, traces that
look like they're not stuck to the PC board any more, cracked components
- particularly diodes do this crack-straight-across thing, it's maddening.

Visual inspection for burned, loose, corroded, or broken bits can get
you a long way. Look closely, a magnifying loupe might actually be a
good idea if you think a molex connector solder joint might be cracked
across, for instance.

This kind of thing at the moment is my best advice. It gets the easy
stuff, the obvious "Oh, that's hanging loose." things out of the way.

And if you don't find any, I'm going to drop out and listen, OK?

530 does NOT have a plug either.
Only the 520 and 820 radios require the 9 pin plug with pins 8 & 9 jumped.

Check if the screen grid switch is in the ON position on the back of the transceiver.
If in the OFF position Final tubes cannot draw current as they are biased OFF.

> Any thoughts on how to bring her back to life?

A thought, but DON'T do it, from the early days of the personal
computer. Amiga computers, to be specific. Manufacturer's bulletin
came in, problems in a whole batch of their newest claim to fame. The
solution (PLEASE DON'T DO IT!!):

Lift the box a measured six inches off of a firm desk or table surface.

Let go.

(Seems that it seated some chips that weren't quite in their sockets.
Valid fix, it worked a treat.)

Instead, first I'd check the jumper plug on the back and make sure it's
in there good and snug, maybe pull it and replace it a couple of times.
Then if it still doesn't play nice, I think I'd open the case and
inspect the molex plugs, maybe pull them gently (straight up, isn't it
Terry?) and see if there is not some corrosion on there that exercising
them didn't break off and polish. Gently. No need to make a small
problem into a big one.

Seating the tubes in their sockets is next, watch for the high voltage
inside the PA cage and all that.

That's where I would start. If the folks here who have done this longer
than me have a better idea, go with what they say instead. But I'd
check for corroded or oxidized connectors first.

Then I'd check to see if the tubes had gotten gassy.

Good luck with it.

Wes,

What jumper plug on the 530? I've only got din plugs on the back of mine and this is the first time I've heard about jumper leads

Whoops. Sorry. 830. I thought it said 530. Never mind the jumper.
Wrong model.

If you're up to checking the board connectors without zapping yourself on the HV section, I'd at least inspect them for any signs of corrosion. 900vdc HV reading is spot on, so the resistors and caps in the PA cage are probably OK, likewise the choke in there. Best stay out of the PA section until and if it becomes necessary.

Do you have the service manual downloaded for your rig? Check for the proper bias voltages on the test points it shows. I don't have that radio, never even seen inside of one, so I can't be specific here. (There are various values, the 9vdc for most of the boards with IC's and transistors (VCO, VFO, Balanced Mixer section, all of that.)

If you've got the high voltages, and the bias voltage levels from the power supply/rectifier board, and none of the connectors is corroeded, cracked, or lifted off the board, then we're at the point I drop out of here and learn from the experts while they talk you through finding what went south during the last 15 years.

I could download the schematics and the service manual for your type box, and try to fake it, but I'm not that big a fool. And I do NOT want you to make a very-likely small problem worse with me bumbling around all thumb-fingered and foolish. Check visually for anything that looks as if it might be corroded.

Dull solder, whitish powdery stuff on a molex connector, traces that look like they're not stuck to the PC board any more, cracked components - particularly diodes do this crack-straight-across thing, it's maddening.

Visual inspection for burned, loose, corroded, or broken bits can get you a long way. Look closely, a magnifying loupe might actually be a good idea if you think a molex connector solder joint might be cracked across, for instance.

This kind of thing at the moment is my best advice. It gets the easy stuff, the obvious "Oh, that's hanging loose." things out of the way.

And if you don't find any, I'm going to drop out and listen, OK?

Dave,

Are you getting any sort of output on your external watt meter in CW or Tune mode? As it has been sitting on the shelf for so many years, when you last used it 15 years ago were then any problems or was it working as per OEM? Lets go back to basics and I'll ask a stupid question, do you have HV on the meter, if so what is the voltage? Are you able to see if the tubes are actually glowing? If IP is OK do you have any ALC meter movement? Do you have any reading when in RF meter position? Report back with your findings and we can move forward one step at a time.

Subject: [TS-520_820_530_830] TS830S, no plate current

My 830's been on the shelf for 15 years and I fired it up today to check it out. Here's as far as I got:
* Verified bias is 60ma
* Tuned for ALC, LOAD full CCW, CAR has to be set at 9 oclock to stay in the ALC range
* Tuned to dip plate current, meter reads zero all the time.
* SG switch in back is ON.

Any thoughts on how to bring her back to life?

44257. Problem adjusting balanced modulator TS520SE

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-24 11:46:24 UTC
From: adrian.langford@ymail.com
Topic: 44257 Message: 44257

I got hold of a good calibrated AF sig gen recently, so was keen to carry out the Section 17 in the TS520S service manual Balanced Modulator and Carrier Adjustment.

You first peak the output on 20m, then inject 1500Hz (5mV) at microphone and adjust Mic control for 50W out. This went fine.

Then I switched input to 400Hz. You are then meant to peak TC3 on Carrier board for output 45-55W. In fact I found TC3 could only peak the output power at 40W (Welz power meter) which is closest I could get to 50W.

Then you dial up input to 2600Hz, and the manual says you adjust TC3 again to get close to 50W. But having adjusted for 400Hz the power out indicated at 2600Hz is only about 10W. If I adjust TC3 to get close to 50W then the power out when I check back at 400Hz is down to 10W! This is all on LSB as per manual (but on the bands you would use USB obviously).

I'm worried that if I can't get roughly equal power from 400Hz through to 2600Hz, then this might affect audio quality (haven't been able to monitor it, but haven't had any compliments!) as well output power if it's dropping off at one end of range. I'm also confused about why there is a single control to match power out throughout frequency range, as if it needs big adjustment at one end of range then that throws other end out! At the moment I can only choose to have either the low or high frequency output roughly match the output at 1500Hz input, not both.

Where would I start looking to solve this problem? Seems like SSB output should be pretty constant through voice frequency range, but I'm not achieving that.

thanks in advance.

Lots of good intentions here. Daves advice to go back to basics is good. Lets look at what we believe we know.

The fact that you can adjust resting plate current to 60ma tells you:
1. Filaments are lit.

2. Cathode resistors are not open and you have emission from finals.

3. Screen grid switch is in On position and working. Working means it has transitioned from -100vdc to + 260vdc or so. Fellows please if SG switch wasnt on and working he would have no resting plate current as the tubes are cut off by high negative voltage applied to the screen grids. This is done so you can "cold" neutralize the finals. Sometimes when switch is turned to on it does not make the needed transition so you need to exercise the switch. In this case switch has to have good contact as he has 60ma resting plate current.

4. Ip meter switch contacts are good.

5. If you get full scale deflection in the ALC box in Tune at 0900 Car Level this means you have good Driver tube,rf drive level at 6146 control grid is exceeding the dc bias offset voltage, ALC amp circuit is working, ALC bus voltage is being lowered, meter circuit sees it and drive meter up scale.

By the way no reason to keep the indication in the ALC box. ALC black box has no meaning while loading the rig. Bring CAR level pot up to give yourself a decent indication where you can see the peak. 2/3 scale is a good spot. You are tuning the TX Mixer and Driver Tube tank circuits to resonance (max rf voltage) and not setting a grid current level. This is a Class AB1 linear not a Class C amplifier. The moment there is a hint of grid current the ALC reduces the TIF amp signal to the TX Mixer. Max grid current is around 40ua. You cannot hurt the 6146 final grids contrary to what some people believe and teach.

6. Having 900vdc on panel meter tells you the HV rectifier and caps are good and HV meter string is good. Does not tell you that you have 900vdc at anodes of the 6146 final tubes. Most likely you do as Plate choke should not have failed while sitting in storage.

7. What happens if you try to make your initial plate current dip in CW mode and not Tune? Pre-position the Plate Tuning cap on the white arc for band you are loading in, meter in Ip position, place hand on Plate Tune control, Flip to send and be prepared to quickly adjust for plate current dip. Do not allow current to peg FSD for more than second or so.

Report back this result.

44259. Re: Problem adjusting balanced modulator TS520SE

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-24 12:32:09 UTC
From: adrian.langford@ymail.com
Topic: 44257 Message: 44259

I've just measured output power over range of input frequency 400-2600, having set it at 50W for 1500Hz, and got it as close as I could at the 400Hz end:

the power at 400Hz is about 40W, but it dips to 20W at 600Hz as you raise frequency to 1000Hz where it's back to 50W.

Stays flat at 50W up till 1800Hz when it's dropped to 35W. At 2400Hz it's 20W, down to 10W at 2600Hz.

So the big drop in power at top end is after 2200Hz so perhaps I should live with that. But I'm puzzled by the dip in power between 400 and 1000Hz.

Has anyone checked their output power across input range to compare with these readings?

Topic: 44257 Message: 44260

Adrian:

The manual like all is not clear. You have to think about what you are doing. What is the objective of each adjustment?

1.Null balanced modulator carrier equally in LSB and USB mode.
2.Adjust the 3dB roll off points of the filter response. Some call it setting the Carrier point.

So it is a two part adjustment. First you are nulling the carrier to balance the null equally between LSB and USB. I use a PL-259 connector with 2 100 ohm resistors in parallel from center connector to shell. This gives me a place to connect my RF millivolt meter or O-scope across to measure the rf voltage. It requires several back and forth adjustments to get the carrier nulled as low as you can and equally low on LSB and USB. It will be a compromise. Once that is done remove the PL-259 dummy load and connect rig back to main dummy load. Now ready to do "Carrier Point" adjustment.

The reason you inject mic level for approx 50 watts output is the procedure takes relatively long key down times so they picked 50 watts so you arent stressing the finals. 50 watts isnt a magic level. 40 watts is ok. A even graduation on your wattmeter is what you need.

Now what is not clear is that you are adjusting the 3dB roll off points. That means half power points. So if you have 50 watts at 1500 hz then you want to see approx 25 watts at 300hz and 2600hz. You adjust TC3 carrier osc frequency trimmer in LSB and TC-2 in USB for 25 watts output.

Some people use 400hz and 2700hz. It depends on what kind of audio you like to listen to and like to be heard. Some like more bass sound (300hz) and some like more treble sound (400hz).

So dont try to adjust for within 5 watts of 50 watts at each 3dB roll off point. 3dB is the half power point. It should say 1/2 or 50% of the 50 watts (or 40 watts) you had at 1500hz. Some folks use 1200hz as it is approx 1/2 of the 400 to 2700 hz response but 1500hz works fine.

Try this and report back. Since I do not run an amp I usually set for more communications audio which means a little more treble than base. Just remember how it sounds in receive is how it will sound in TX.

Terry that's brilliant thanks so much.

So the manual is misleading on not going for 1/2 power at the -3dB points. Also if I understand correctly you do the low roll off with TC3 set to LSB, then switch to USB to adjust TC2 for the high frequency roll-off? Again manual doesn't mention switching Mode having mentioned LSB.

I'll be sure to rebalance the LSB and USB after trying this. My dummy load has a case which comes off easily and I can measure across it once that's off. When I did the carrier balance originally I just put the scope across the ANT terminal, as the manual implied you removed dummy load to do this.

Will go through all the adjustments again later this afternoon and report back.

Thanks again and 73. I will make a note in my copy of service manual too.

> >
> > Then I switched input to 400Hz. You are then meant to peak TC3 on Carrier board for output 45-55W. In fact I found TC3 could only peak the output power at 40W (Welz power meter) which is closest I could get to 50W.
> >
> > Then you dial up input to 2600Hz, and the manual says you adjust TC3 again to get close to 50W. But having adjusted for 400Hz the power out indicated at 2600Hz is only about 10W. If I adjust TC3 to get close to 50W then the power out when I check back at 400Hz is down to 10W! This is all on LSB as per manual (but on the bands you would use USB obviously).
> >
> > I'm worried that if I can't get roughly equal power from 400Hz through to 2600Hz, then this might affect audio quality (haven't been able to monitor it, but haven't had any compliments!) as well output power if it's dropping off at one end of range. I'm also confused about why there is a single control to match power out throughout frequency range, as if it needs big adjustment at one end of range then that throws other end out! At the moment I can only choose to have either the low or high frequency output roughly match the output at 1500Hz input, not both.

Yes you are trying to get equal rolloff at 300hz and 2700hz and if you can get that within approx 5 watts of 25 watts (assuming you used 50 watts at 1500hz) that is your objective. This is where they came up with the 5 watts tolerance noted in the service manual.

You do not know what the center frequency of the filter is and you cannot change that. You cannot just set the carrier osc frequencies to 3393.5 for LSB or 3396.5 for USB.

There are other methods that can be used but audio in the mic line is probably the best:
1. Use Marker signal and S-meter. Richard Measures describes the method in the TS-830S survivors guide in the maintenance section. It works pretty well if you do not have an audio generator.
2. Can set if by ear if you have a good ear!
3. Use Laptop PC and audio spectrum analyzer software like Spectrogram and a diode noise bridge. This works very well and nice to see visually the filter response. Lately I have been using this method.

I have never seen the IF filter response curves published by Kenwood. Not sure they exist. To see them you need:
1. Spectrum analyzer and tracking generator
2. Two port VNA
3. Sweep generator and marker generator.
4. Can plot on graph paper the old fashioned way with RF sig gen and RF millivolt meter or O-scope but is tedious method.

I usually start in USB but it doesnt really matter.

No... you stay in LSB and you go back and forth from low freq to high freq and adjust the same trimmer TC-3 until you get the roll off close to the same at both low and high ends. You then switch to USB and do same thing with the other trimmer TC-2. That is why the approx 5 watts tolerance is noted. So it will likely be greater than 25 watts at each end. Just make them equal.

> So the manual is misleading on not going for 1/2 power at the -3dB points. Also if I understand correctly you do the low roll off with TC3 set to LSB, then switch to USB to adjust TC2 for the high frequency roll-off? Again manual doesn't mention switching Mode having mentioned LSB.
>
> I'll be sure to rebalance the LSB and USB after trying this. My dummy load has a case which comes off easily and I can measure across it once that's off. When I did the carrier balance originally I just put the scope across the ANT terminal, as the manual implied you removed dummy load to do this.

Ron:

Enjoyed talking to you. Sure wish you had thrown rig in truck on your run north from Nashville. Congrats to you and your son on your new tickets. You can surmise from discussion on the forum you have taken on a challenge by purchasing a Hybrid right out of the chute. I understand that you have some electronics background which should help you. If you cannot get the 820 working locally then on your next run north swing by and will put on the bench and will see if we can get it going. No charge for that. If you have to leave it then we can discuss my fee. I no longer use a hourly shop rate. At $40/hr you can very quickly rack up more than rig is worth. I charge a flat fee that includes complete factory alignment and a 90 day warranty.

Here is summary of what I recall us discussing:
1. You placed a wire jumper from pins 8 and 9 in lieu of the mini jumper plug. I suggest you check that again as the wire gauge may be too small and not making good contact. Also, make sure you are on the small 9 pin socket and not the big octal socket. If you have top off rig might want to use a alligator or mini-grabber jumper and jump across pins on the back of the mini socket. Just need to be 100% sure on correct pins.

2. I think you said you have the remote VFO-820? If so, I would plug it in and see if rig comes alive. Remove 8/9 jumper placed on rear of the socket if you do this.

3. You seemed confused about what having no Marker signal is telling us. When I said because we have no Marker signal we now know the SO-239 connector, TR relay contacts, xvtr switch, and rf attenuator switch are not the cause of no receive I meant just that. The Marker signal comes in down stream of this normal off air signal path. The normal path goes thru these components and then goes to the Coil pack board to the step-up transformer. The Marker signal goes directly to the Coil pack board. You are using the Marker signal as a RF signal generator to test the receiver.

4. If you are certain that you have good 8/9 jumper and no receive and no transmit then next thing I would check is the VCO signal at RF board. You indicated you have an O-scope. Go to RF board Conn RF-1 pin 4 and measure the VCO signal. Signal level should be approx 1 volt rms or approx 2.8 volts Peak-Peak. On 40 meters will be approx approx 16mhz and on 20 meters approx 23mhz. So set your sweep time base fast approx .05us to see nice sine wave. If no VCO signal might want to exercise the Tune Normal switch on VCO board but typically not a problem.

5. If no VCO signal then next thing I would check with O-scope is VFO signal at Pin 1 of the external VFO jack on rear panel. Should be approx 1volt rms or 2.8 volts P-P on your scope. Set time base to approx 0.2us for clean sine wave. With VFO at 200 should be approx 5.3mhz. Also should check to make sure it is available at the PD board (PLL). Most likely if at ext jack will be at PLL. If no VFO signal at PLL then no VCO and no VCO means no RX or TX as both mixers on the RF board will not have the required local oscillator (LO) signal.

I believe that is what we discussed. Again you told me that you are aware and comfortable working around 900vdc and 300vdc present in this radio but I feel compelled to caution you again.

You can call me any time between 7:00 am and 10:00 pm if you want to discuss as a little easier than typing!

Ron:

I forgot to summarize our discussion on attempting to load and adjust SWR on the Hustler vertical. Lets reserve detailed discussion once you get the receiver working and hopefully the transmitter at same time if it is a VFO problem.

Very briefly:

I dont know of anyway that you could have caused loss of receive while loading in to this vertical. Also, you dont need an analyzer to adjust it. Nice tool, but not a requirement. Hams have been adjusting verticals for years with SWR bridge, but in my experience the old fashioned Diode Field Strength meter is better tool. Dummy load has nice low SWR but not good radiator. Same with verticals can get the SWR down but that doesnt mean it is radiating effectively.

Anyway you mentioned you began seeing power fall off as you tried to tune the Hustler. It is possible that with many repeated key down cycles that you could have seen emission falling off on the Driver tube and the Finals. They will get hot if using full power to tune an antenna. The tubes could be getting soft. Also, you may want to do a visual inspection inside the PA cage with HV caps discharged to make sure RF choke does not appear overheated and bypass cap at its base not overheated. Again do this after get the receiver going.

Please dont jump back and forth between receiver troubleshooting and transmitter troubleshooting.

I can give you a Driver stage test later that you perform with SG switch off that will tell you the condition of the 12BY7A.

Lastly, SWR will not burn up your 6146 final tubes as some persist in thinking and teaching nor can it effect the receiver circuits. About worse thing that can happen is if you have a very high impedance at the SO-239 or an actual open coax connection. If that occurs can have very high rf voltage across the Plate Load cap and it could arc over. Manual will tell you need to have under 2:1 SWR but that is a very conservative statement. As long as you have the range in your Pi-network caps and can adjust them to address the reactive component there is no worry about hurting the rig and certainly not the receiver. They may not align exactly to marks on the white arc but that isnt important.

Focus on making sure you have good VFO signal and then good VCO signal if restoring the VFO doesnt fix your problem.

Please report progress on recheck of 8/9 jumper, trying the remote vfo, measuring VCO and VFO signal levels.

OK I think that covers everything we discussed. You might want to print these notes.

Terry K9TW

Thanks for the info Terry, I think we're onto something.
I set the CAR control about 2/3 up and keyed in CW mode. Now I can dip the plate and get about 300ma Ip and 100 watts output. That makes me feel a LOT better. So why can't I get Ip in TUNE mode?

BTW, the fan is a bit sluggish, I think I'll pop it out and lube it, and I want to put a 3-wire power cord on it. Any problems with doing that in your mind?

Tune? Pre-position the Plate Tuning cap on the white arc for band you are loading in, meter in Ip position, place hand on Plate Tune control, Flip to send and be prepared to quickly adjust for plate current dip. Do not allow current to peg FSD for more than second or so.

Well, at least now I have a reference point. My 520 has no idle current and an oddity of other tune readings. (I can see a very small filament light as far as I can see through the HV cage. Removing it this afternoon for a better look.)

Look forward to following along. Thanks!

-O'B.

Forgive me if I replied twice, I sent a reply earlier but it isn't in the list yet.

Ok, when I hit Send in CW mode I can easily dip the plate and get up to 300 ma Ip. Output power on wattmeter is 100W. So why no luck in TUNE mode?

Most likely R15 (56K) on the rectifier Board is open which will stop you
from getting IP in Tune Position.

Thanks Terry I've just gone through the adjustments.

It is tricky equalising the low and high, but I found that on LSB and USB, using the procedure you explained here (only adjusting the relevant trimmer for that mode), I could get the low and high (I chose 400 and 2600 to both kick out 15W with the 1500Hz producing 40W.

Thank you for guiding me through this and pointing out error/omission in service manual. I have annotated that section accordingly.

One final thing that puzzled me is that I did the final adjustment asked for where on CW (no SG) you check with counter that the CARRIER OUT is set to 3.395MHz. I couldn't adjust the trimmer TC1 to any lower than 3.19518 or crystal would stop oscillating. I though the trimmer would let me pull the xtal either side of 3.395?

Thanks again and 73s Adrian G4IQW

PS I also followed up with nulling the 2 sidebands, and got them very close to each other. Both the TC1 and VR1 adjusters on the Generator board are really sensitive when near the minimum (I used my scope across the dummy load).

I am not sure what you are trying to do. A trimmer cap placed across a crystal (in parallel or shunt) is typically used to move the frequency down. A cap in series is typically used to move the frequency up.

When you increase the capacitance of TC-1 its capacitive reactance goes down so you reach a point where the impedance is so low you have essentially shorted out the crystal and the oscillator will stop.

Are you trying to adjust it below 3.195? OR Just wanting to see how much you can pull it? Are you really wanting to move it up to get a 800hz beat note instead of 700hz?

Adrian

Are you certain that your Audio Generator level is not varying as you adjust the frequency from 400hz to 2700hz. How are you measuring the 5
mv level. Some audio generators do not hold the level constant as you move up and down frequency. 5mv is a very low level and wont take much change in audio input level to produce change in output power.

I place a bnc tee at my audio generator output and couple one side to a true RMS ac voltmeter (HP3400) and the other side to the rig mic input that way I can set it right on 5 mv or 7mv and then keep and eye on it especially at low and high end where you need to make the adjustments.

Before suspecting problem with your filter response should make sure MV output from audio generator is constant.

> >
> > Then I switched input to 400Hz. You are then meant to peak TC3 on Carrier board for output 45-55W. In fact I found TC3 could only peak the output power at 40W (Welz power

meter) which is closest I could get to 50W.
> >
> > Then you dial up input to 2600Hz, and the manual says you adjust TC3 again to get close to 50W. But having adjusted for 400Hz the power out indicated at 2600Hz is only about 10W. If I adjust TC3 to get close to 50W then the power out when I check back at 400Hz is down to 10W! This is all on LSB as per manual (but on the bands you would use USB obviously).
> >
> > I'm worried that if I can't get roughly equal power from 400Hz through to 2600Hz, then this might affect audio quality (haven't been able to monitor it, but haven't had any compliments!) as well output power if it's dropping off at one end of range. I'm also confused about why there is a single control to match power out throughout frequency range, as if it needs big adjustment at one end of range then that throws other end out! At the moment I can only choose to have either the low or high frequency output roughly match the output at 1500Hz input, not both.

Sorry my typo putting 3.195

I meant 3.595 which the manual says to set the CW trimmer TC1 on Carrier board to.

But the xtal stops oscillating at about 3.19518 according to my frequency counter, so I can't set to the precise frequency specified

Hi Terry

I posted about the odd power dip before you helped me with correct procedure. I had been trying (and failing) to set output power same for 400, 1500, 2600 audio in.

Now I have followed your instructions the power varies smoothly from 15W out at 400 in, through peak of 40W at 1500 (set using Mic), then back down to 15W at 2600Hz. This is in LSB and USB.

So the filter seems to behave ok. But to answer original question I got to 5mV by adjusting for 14mV p-p (5 x 2.8) on my scope. I checked at the 400 and 2600 points and the output was same going on the scope waveform.

73s Adrian G4IQW

AArgh more typos on iPhone keyboard!

The manual says set the CW trimmer TC1 for 3.395

I can get down to 3.3952 but then stops oscillating, so I can't get to 3.395MHz precisely.

Sorry to cause confusion!

Adrian

Ok you are saying you cannot set CW transmit carrier oscillator any lower than 3595.18 where it stops oscillating.

How do you know your counter is accurate? Do you have any kind of 10mhz reference standard to check cal? Iso-temp 134-10 OCXO or Rubidium standard?

Do you have another transmitter that you think is reasonably accurate that you can sniff its output?

Can you copy WWV well enough to zero beat counter clock against?

As you can see I am suspicious of your counter.

Terry

Ok Adrian I am getting my posts mixed up! Maybe a knot in the cord across the pond!

Sounds like you have it now. One more thing to check is to flip back and forth from USB and LSB and listen to the back ground noise tone. It should sound very nearly the same. One should not be more bass or more treble than the other. This isnt real precise unless you have a discriminating ear or good musical pitch.

You can also turn on the Marker and zero beat it until you get a nice slow rhythmic flutter of the S-meter needle with the AGC in Fast. You need a delicate touch on VFO knob. Maybe just tap on it as you get close. So in LSB you may have the near zero beat slow flutter at around S3. When you flip to USB should have very nearly same S3 flutter. If the flutter stops or is not at S3 then you do not have LSB and USB response adjusted the same.

Bozhe moj. SO simple. And that would have been SO much easier in the field back when I was humping a receiver (and transmitter) through the mud in Germany, jammer box, crypto "green" commo section, and loop antenna....

I had to do all KINDS of 'field expedient' repairs to keep that "AN/TRQ-30" "Turkey Thirty" receiver in some sort-of-working order, and getting USB and LSB reception somewhere NEAR evenly calibrated was not on the list of things I could bother with. I wasn't even supposed to open the derned thing, "NOT YOUR MOS, ZOOMIE! Hands OFF!!" But my rig was the only one working all too often. (I was the pet zoomie in an MI Battalion, life was NOT exactly a bed of roses anywhere I was. Excepting the thorns, I guess.)

The transmitter was a separate box, and the whole MESS rode on top of Alice, who rode on top of me, and it was NOT a sensual joy, that relationship. (I'm not into pain. You wouldn't have known it from some of the things we did to keep the top brass all happy-happy and OFF our butts.)

Watch the flutter near null, flip to the other half. Heilige Schaffenscheisse, Fliedermausmensch. How could I have missed THAT one.

Many thx for the info Gordon. I checked R15 as you suggested. It looked totally normal. Then I tested it with ohmmeter in circuit and it seemed a little squirrelly. So I powered up and checked voltages. SG2 on one side of R15 had plenty of voltage. The other side of R15 was zero volts. So I pulled R15 out of the board and sure enough it's open. I'm short on resistors and went to the local radio shack..No luck. Will have to wait until Monday to get that 56K resistor and will update then.

Wes:

You can read the method in the TS830 Survival Guide under the Maintenance Section Step 8.4 for LSB/USB carrier oscillator adjustment. Not everything in these kinds of guides is valid and should be done but this one does work.

Method isnt as accurate as injecting audio and using wattmeter to set the roll off or using audio spectrum analyzer software, but if done carefully it works well.

On the TS-530/830 rigs Kenwood provided access holes on bottom of the chassis so no requirement to remove the covers. I call these kinds of adjustments "user preference" adjustments as how the rig sounds is "subjective".

Some like the more bass sound, but if running barefoot a more communications style audio might serve better in bad band conditions or when chasing DX.

By the way just moving your hybrids around in the shack can cause the carrier oscillator trimmer caps to change position.

Hi Chuck:

Well I dont know how well it would work as both the Operating and Service Manuals are full of drawings on just about every page.

All I really need is Section 6 of the Operating Manual and the Adjustment Section beginning on page 43 and ending on page 53 of the Service Manual.

If you would like to try conversion and see how it comes out could you go to W0NTA website and download the manuals? Dick has very nice enhanced copies on his site.

If you can do that and the text comes out good so I can start revising them to fix and add missing info I will do that as time permits. As I recall there may be a missing figure or wrong figure called out but if that is only thing we cant correct not a big deal.

If this doesnt work I would have to take Daves suggestion of typing up one line entries detailing the fixes sort of like errata sheets.

This is reassuring as the white noise tone is almost identical USB/LSB.

I also tried that s-meter twitch and again switching between modes the twitch stayed same and the needle didn't move from just under S3 where the twitch started.

Guilty your honour! I can't be certain the counter is accurate on that range. But it is accurate when I sniff RF from xtal controlled 221 rig (eg 145.5 reads as 145.49999 or similar).

If my CW mode crystal is at 3.3952 instead of 3.395 are there any practical consequences?

The 520SE is very accurate whenever I calibrate to marker. Freqs I read for stations heard are as reported to DX Spot pages, and nets are spot on.

I can rarely copy WWV at least not in daytime. I will check again tonight to see if I can hear it but it's never there when I look for it, despite peaking 15MHz receive as per manual.

Adrian:

I am not saying it is not possible that you have a bad crystal. I just havent seen it with Hybrid carrier oscillator crystals. I have seen poor soldering at the pins on carrier and het osc crystals.

I am not a crystal expert. I know they drift with age and some manufacturers pre-age them. Pretty sure they can drift either positive or negative with age, but not sure which is more predominant. Not sure how they would get contaminated inside the can, but could see where holder mounting stress and/or being excited all these years could cause drift.

In the old days I would remove the quartz crystal from the FT-243 holder and take one of moms picture frames apart to get the glass plate and would mix up a lapping compound paste of Ajax or Comet bath cleaner and gently "figure 8" the crystal to move it. If moved too much then take magic marker and "pen" it. Worked great. Pretty hard to get to the crystal element in these metal sealed can units. Never cut one open.

If certain that your counter is accurate then might contact Bob Mansker and see what he gets for a Carrier Osc Board. I dont know if ICM makes them or not? Maybe Mike W5RKL knows?

I cant think of a problem with not being able to pull xtal to exactly 3395 other than if you are close to oscillator quitting. I would be concerned if the carrier output level is too low for good LO action at the mixers. Should be between 800mv to 1.0v. I would compare its output against LSB and USB. Measure it with RF probe/VTVM/DMM or O-scope. With O-scope will be approx 2.3 to 2.8 rf volts P-P.

> Very briefly:
>
> I dont know of anyway that you could have caused loss of receive while loading in to this vertical. Also, you dont need an analyzer to adjust it. Nice tool, but not a requirement. Hams have been adjusting verticals for years with SWR bridge, but in my experience the old fashioned Diode Field Strength meter is better tool. Dummy load has nice low SWR but not good radiator. Same with verticals can get the SWR down but that doesnt mean it is radiating effectively.
>
> Anyway you mentioned you began seeing power fall off as you tried to tune the Hustler. It is possible that with many repeated key down cycles that you could have seen emission falling off on the Driver tube and the Finals. They will get hot if using full power to tune an antenna. The tubes could be getting soft. Also, you may want to do a visual inspection inside the PA cage with HV caps discharged to make sure RF choke does not appear overheated and bypass cap at its base not overheated. Again do this after get the receiver going.
>
> Please dont jump back and forth between receiver troubleshooting and transmitter troubleshooting.
>
> I can give you a Driver stage test later that you perform with SG switch off that will tell you the condition of the 12BY7A.
>
> Lastly, SWR will not burn up your 6146 final tubes as some persist in thinking and teaching nor can it effect the receiver circuits. About worse thing that can happen is if you have a very high impedance at the SO-239 or an actual open coax connection. If that occurs can have very high rf voltage across the Plate Load cap and it could arc over. Manual will tell you need to have under 2:1 SWR but that is a very conservative statement. As long as you have the range in your Pi-network caps and can adjust them to address the reactive component there is no worry about hurting the rig and certainly not the receiver. They may not align exactly to marks on the white arc but that isnt important.

44292. KENWOOD HYBRID USER NET (August 25th, update)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-25 18:38:56 UTC
From: mvgilger
Topic: 44292 Message: 44292

The Saturday's net on 40 meter we had 14 stations checking in under good band conditions. There were 3 new check-ins, WQ2A, KB3FWW, and VE3JEA. Out of those, there was:

2 running TS-520(x)
1 running TS-530(x)
5 running TS-820(x)
3 running TS-830S
0 running TS-900

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 8 stations checking in under good band conditions. Out of those, there was:

4 running TS-520(x)
1 running TS-530(x)
0 running TS-820(x)
1 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39
April 2013, Saturday's net total = 52, Sunday's total = 29

May 2013, Saturday's net total = 45, Sunday's total = 50
June 2013, Saturday's net total = 30, Sunday's total = 27
July 2013, Saturday's net total = 63, Sunday's total = 41
August 2013, Saturday's net total = 62, Sunday's total = 43 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

73's,
Mark, WB0IQK

Ron:

Thats great news. I have had same thing happen so I usually take a jumper test lead and connect 8/9 at rear pins of the tube socket which gives you a good positive connection and allows you to look at the leads landed on it.

Search on Message 40016 to see the Driver tube test. If you cant find it then let me know. Only thing I would add to it is to let the Driver tube rest a little bit in between each band test. The Driver tube is running Class A and right up against its maximum plate current so it gets pretty hot. I have never had one fail during this test, but it is possible. You will need to increase CAR Level on 10 meters and may not be able to get full scale deflection (FSD). Just peak it for max and watch it for a few seconds to see if ALC slowly drifts lower under keydown.

If the Driver tube passes this test then it is possible that the power drift that you witnessed is due to your finals getting a little soft. I usually measure all the 6146 dc voltages at the tube socket pins on the final board to make sure they are to spec and not drifting off under key down. Very seldom see any of these voltages fall off under key down. Screen grid is most important.

I know fellows who have run literally for 30 plus years on same set of S2001 and 6146 finals and they may not be able to get 100 watts out at spec plate current anymore, but they continue to use them as CW and SSB it is not a high duty cycle mode and 80 watts output is OK.

When I start to see approx 70 watts out on 20 meters I recommend to the owners that it is time to change the finals. I rotate my spare finals so I never see less than like new output. Dont forget if you change them you will need to neutralize. You can use your O-scope for that. I would recommend 6146B or 6146W and no need for a matched set.

Let me know how Driver tube works out. Ken K4EAA sells pulls and NOS 12BY7A tubes on his site. No need to neutralize after changing driver tube. Be careful removing the tube shield. Sometimes the ground strap bonds and seizes to the shield. Take a mini screw driver and spread the shield slightly at the split and work it off the tube. Maker sure ground strap is inside it when you slip it back over the new tube.

Wow
KB-1 knob sold for almost $300 bucks
I am lucky to have one on my TS-830s and one on the matching VFO
That would make $600 dollars before i even put a price on the radio and
VFO,if i was to sell them.
Just replaced a dial lamp in my TS-520s,,that was a blast.
Cleaned the front panel and all the knobs with Mr Clean,,,,years of
germs collected on it.
Hybrid guy forever.

> Wow
> KB-1 knob sold for almost $300 bucks

Wow, indeed. That's just plain NUTS.

Me, I've got a Dremel tool, and a drill press which will make nicely-symmetrical holes in the original knob, and a torch that will quite easily melt lead or pewter with which to fill them. Oh, and a lawn-mower-blade balancing cone which very likely would do to balance a plastic knob filled with lead, should I feel the need to get a heavier knob.

Three hundred clams for a knob, even an undoubtedly very NICE knob, is just silly.

That sort of thing is for folk with more money than good sense, is my opinion.

Yes, it's their money, and they're more than welcome to do with it what they please. But you would think with the application of just a LITTLE intelligence something better might be done with it, wouldn't you?

(In the same vein, you don't -even- want to get me going on the money-wasting, gas-guzzling, 4-wheeled bung-holes known as "Hummers." Or their owners.)

But that's nothing to do with hybrids. Putting the rectifier board back into a 520SE, however, is. Made a start on that today, as a break from tweaking and repairing all the test equipment that is waiting on the bench for my attention.

My enduring thanks to Bob for leaving a tag-end of the original wires, with the colour code visible on the insulation on the wire-wrap posts of the rectifier board he sent me.

That, sir, was a rig-saver. Having to trace each and every individual wire back to where they connected on the other end, then checking them all against the schematic, well, 'time-consuming' wouldn't cover it. I would have done it, had you not left enough wire on the new board to be certain of the correct attachments. With my notes and the pictures I took, along with that little tag-end clue, the odds are a lot higher that I got things on the right peg.

Plus, I'm chasing down as many of them as I can anyway, just to get more familiar with the innards of this thing. It appears that once it's working I can likely leave it alone a long time, and just use it. But then again, sometimes things just go "Pop!" and the magic smoke leaks

out, so knowing where I'm going will never be wasted time or effort.

44300. TS-520SE RECEIVER RF SECTION ALIGNMENT QUESTION.

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-08-26 20:33:08 UTC
From: Charlie
Topic: 44300 Message: 44300

I finally had my first opportunity to open my 520SE and decided to perform the alignment as described in section 6.3 (Receiver RF Section Alignment) but ran into a potential problem right off.
While adjusting the 1.8 MHz antenna and mixer coils I observed that there was no change in the S-meter deflection whatsoever. The coil slugs are moving and I've re-read section 6 numerous times but I am unable to determine why there is no change in the S-meter. I stopped at this point rather than proceed to the next set of coils.
The stand-by switch is in REC, dummy load attached, SG switch is on, the VFO plug is in and functional, Drive set to 12 o'clock position, RF ATT off, RIT off, Function switch to CAL, and the S-meter functions normally.
Please be advised that I have a "gift" of missing the obvious at times but this really has me puzzled. Why no meter movement?
Is there some setting of a switch or dial that I'm overlooking?
Is there something that I'm missing that is "understood" but not specified in the manual?
Why is there no S-meter response?

You said you set the FUNCTION switch to "CAL"?

What "position" is the Function switch knob pointing to?

1. 25Khz
2. RMT
or
3. FIX

The FUNCTION switch knob should point to "25Khz" not "RMT" or "FIX"..

Have you tried "listening" for the Marker signal on other bands?

There were no symptoms, Mike. The rig was performing just fine. I just had my first opportunity to open the case and wanted to take this opportunity to perform an alignment to ensure everything was as it should be. I'm so fond of this radio that I'm selling my TS-940 and, while I was replacing the 940 with the 520, decided to open her and look around to become more familiar with the actual location of the boards, etc. A manual is one thing but there's no substitute for "hands on" experience for me.
The "CAL" remark was a poor choice on my part. I should have stated "CAL-25kHz" just like in the manual.
The only solution that comes to mind is that the slugs are broken and just spinning in place. Perhaps the previous owner got too heavy-handed?
I'm a firm believer in "Rule #1, when you find yourself in a hole quit digging." That's why I threw this question out to the group. I was hoping that I simply overlooked something obvious.
Did I?

Gordon:

Glad both pieces are working for you. Always a risk on eBay not being able to see them in operation.

I just bought the new Rigol 1052 digital and it is my first use of a digital scope so jury is still out. I plan to take some key Hybrid waveforms and store them. I had run Tek465 and 475A and 2245A over last 10 years or so when I got serious about Hybrid repair and was planning on getting another used Tek scope, but decided to take a chance on this Rigol.

Glad you have tools now to do the sweeps and alignments of the CE transmitter that you wanted to do. Pretty hard to stagger tune a BPF without sweep gen and scope.

Well I have never measured the IR drop across them but I have measured SG current several times on various Hybrids and get around 21ma at 100 watts out and approx 225ma Ip. If we assume that SG current in Tune mode would be proportional them maybe seeing 4th of that or approx 5ma. So if we assume 125 volts drop @ 5ma then power = 125 x .005 = .63 watts. A 1/2 watt resistor should be able to withstand .6 watts forever. If we had 7ma screen grid current in Tune it would be approx .875 watts. Also the duty cycle is pretty low just the time it takes to peak the Drive and make that initial Ip dip. Seems like a 1/2 watt resistor is speced correctly for this app and should never fail?

I once read on Tom Rauch W8JI site that carbon composition resistors should not be used in power supply voltage divider circuits as they have two failure modes. 1. They are susceptable to moisture in the air and the moisture causes the lead to corrode where it is embedded in the carbon and forms very high resistance contact point or an open. AND 2. With elevated temperatures carbon composition resistors age down in value and in divider circuits this means more current flow and get hotter and age down in value more and get hotter and age down in resistance more and so on until low resistance value and higher bleeder current causes it to eventually short and maybe burn.

I dont know if any of this is documented by the resistor manufacturer app notes or not. I just know I find the Cathode meter shunt resistors more commonly are high in value and have not aged down in value.

So short answer is I dont know why this happens to the screen voltage divider resistors, but as you say pretty common failure.

Terry,

As I have told you, I am not much technician, but in experience over the years with the tube Drakes, Collins, etc rigs I have never seen a carbon comp drift low, always high. Even a cigar box full I left in the storage building where the Okie 115+ summers baked them, ALL were high in resistance. I'd be curious of others experiences with these. Most all of the cathode resistors are way high on Drake tube transmitters, so much so that I keep a bunch just for that purpose. I have gone to the Ohmite OX (or is it OY, memory block tonight) series lately though. Hard to find decent, affordable carbon ones.

Hi Don:

Your experience mirrors mine. I am just reporting what I saw on Toms site explaining why carbon resistors in voltage divider service fail.

My experience with the 56k ohm screen grid divider resistors is that I have found them looking pristine but open or very high in value and I have also found them discolored. To me discolored would indicate heat damage and heat has to be dissipation which means current flow. Now with opens or very high resistance maybe the moisture corrosion at the lead to carbon interface is plausible? I have no idea how this connection is made perhaps just contact pressure?

Perhaps there is a manufacturing defect that causes them to fail after only 35 years in this intermittent duty voltage divider service! Just kidding.

Nothing we need to lose sleep over just would be interesting to understand the failure mechanism. Also most of the time it is just one that has failed. I always replace both.

As Gordon points out pretty easy to trouble shoot. Almost always when you have Ip in CW mode and not in Tune you can bet you have no screen grid voltage and should look at 56k resistors.

Charlie:

Is the rig new to you? If so, no problem wanting to ensure it is at peak RX and TX performance. No way to tell how many tweakers have been under the hood and no point of reference unless have same or similar rig to do AB testing. Kenwood provided Sect 6 in the instruction manual for the owner/operator. Takes no technician knowledge and minimal rf service bench test gear.

To Mikes point one way to check where the RX performance is at is to use the Marker and see what S-meter indication you get on each band. This is a rough test and in part you do not know how well the S-meter has been caled. Normally a 50uv or -73dBM signal at 14.2 mhz is injected and span pot is adjusted to S9. Some people just crank the pot up because they like to see and give nice reports. About the highest it can be set is something under 10 over.

Anyway did you check Marker S-meter indication on each band before embarking on coil pack alignment? If rig is aligned well and you have spec dc voltages to the gain devices and spec AGC bus voltage to gain controlled stages then should see on order of S8 to S9 on all bands with perhaps exception of 10 meters which may be around S6 to S7. If you had these levels then probably wont see much RX performance improvement by running Sect 6. If much lower than this then probably can do some good with a coil pack alignment.

Also does the peak S-meter indication occur at same position of Drive control (1200) as it does when adjusting TX drive ALC indication? This is good indication Drive coils have been pretty well peaked. If not then another reason to do complete Sect 6.

I would start with making sure 9vdc regulated is spot on and RF-1 is set to 3.3vdc.

I would not stop at coil pack alignment. Continue on to the Noise blanker and the select IF transformers and do not touch the ones they note as those require a good signal generator and sweep gen for proper alignment.

In fact at this point I would just do as much of Sect 6 that you can do. It is not uncommon for carrier balance and carrier null/suppression to have drifted off over time. Performing a good Section 6 alignment can put the RX and TX pretty close to factory performance.

As to you not seeing any change in S-meter on 1.8mhz couple of things.
1. Are you 100% certain you are adjusting 1.8mhz Ant and Mixer coils? Easy to get on the wrong coils.

2. If slug was just spinning you would not see it moving up and down in the cardboard former. Make sure you turn it full travel as sometimes folks really crank them to one extreme or other.

I do not have a TS-520S here or I would give you some rough dimensions of the 1.8 mhz core position in the former.

3. If you cannot get any change on 1.8 mhz just go ahead and move on to 10 meters and make sure you follow the remaining band sequence.

Charlie;

One more comment to Mikes point about if not broke dont fix it.

You have to be very careful doing any preventive maintenance on these old rigs. It is pretty easy to induce new failures in them. Sometimes these failures can be immediate such as holding molex connector bodies in your hand that you just pulled off the board or cracking a slug tuned core or twisting the former off its mounts and sometimes can be a latent failure that manifest itself later as an intermittent problem. These are old phenolic boards with plating that doesnt meet todays PC board quality standards.

The radio is of course yours and free to do what you want but if you have never done a coil pack alignment there are some things you should be aware of before proceeding. A good visual is important under good lite. If you see cracked cores or formers twisted and cocked on the boards you need to stop and talk about how to address these conditions. To proceed can result in having a radio that now does not work. Also can help yourself by doing some pre-lube on the cores prior to attempting to turn them. Of course need the proper alignment tool.

Hi all,

I am looking for a BS-8 panadaptor unit to install into the SM-220 that I located here in Spain, because it doesn't equipped with this unit.

I would like to know also the opinion of the members of the Group that have installed this optional unit into your SM-220 and it's useful or only is a "toy".

Many thanks in advance for everything.

Best 73 de David, EC4ACH.

Terry, this has been my backup rig for the past 4 years but is now being promoted to #1, hence my desire to ensure that it's ready and operating as designed
I was following the order of tasks outlined in Section 6 of the instruction manual and, since the S-meter appeared to function adequately, haven't checked it for adjustment but will do so.
I will also follow up on your other suggestions and respond with my results.
I have been able to determine that the coil slugs in question have full range of travel but plan on lubrication of all slugs to prevent any damage.
I also checked the S-meter for movement again while I moved both slugs full range and there was no change on the meter and I have double-checked that I'm adjusting the correct coils.
According to my understanding of coil diagram 6-10, the antenna and mixer coils are the middle 2 coils directly behind the 1.8 MHz oscillator coil. Hopefully, I'm not wrong.
I'm going to lubricate the coils now, wait 24 hours, and get after it again.

Yes, I understand and fully agree. It was not my intent to fix anything but merely to make an adjustment.
I did observe that the antenna coil was slanted in toward the board but it didn't look otherwise damaged and a continuity check of the contacts on the PC board for this coil verified that there was no open.
Oh, I am using the proper alignment tool but it never hurts to ask.
As far as test equipment goes I have 100 MHz scope, VTVM, DMM, RF probe, and an old Heathkit and Eico signal generator. Sadly, my URM-25E fails to generate a signal at the required 50uV so its on the "disabled list" until I can get to it, whenever that will be.
Thanks again, Terry. I hope to have an update in a day or two.

Charlie,

I have a URM-25D that I like very well, and it still works like a charm. It was a fully reconditioned unit that I bought 20+ years ago from Fair Radio Sales.

One additional piece of test gear that I recently added to the line-up here is an Elecraft XG-3 programmable RF signal source. One of the preset levels is -73dBm, or 50uV. Great product...

OK Charlie.

I used a URM-25 in the distant past and it is a good sig gen and more than adequate for your hybrid work. It will pay to fix it and hope it is something simple. Thanks for the update. It helps us know who we are dealing with. Never any intent to question anyones knowledge or ability just need some point of reference.

No need to worry about S-meter cal absent your URM-25. Can zero and when complete with the coil pack alignment just set span trimmer for S9 indication at 14.2mhz and call it good as really only need to use S-meter for providing comparison type reports to the other station for things like when they ask about performance of one antenna to the other or front to back on beams etc. Once you get known 50uv test signal can go back and set the span trimmer.

It is easy to get turned around on the Ant coils as they dont line up with the Het Osc coil markings on the drawing shown toward the front panel. 1.8mhz Ant and Mixer coils are in line with the 28 mhz label toward the front panel and are the coils closer to the band switch shaft and not the outside edge of the rig. Sometimes people see that 1.8mhz label for the Het Osc and think that the entire row is for 1.8Mhz.

They want you to do 1.8 first as it serves as the step up transformer for all the bands except the 15mhz WWV. It is L1 on the schematic. If it were bad you would have very weak or no receive.

Don:
I carried my XG-3 and short bnc jumper and some adapters in my back pack and it sure came in handy to test potential purchases. Generated a lot of questions from sellers.

Terry, it looks like my "gift" of missing the obvious has struck again. I'M ON THE WRONG END OF THE COIL PACK!
After I lubricated the slugs, I came back into the shack a while later to flip the rig so that the lubricant would spread more evenly. I picked up the bottom of the case to put it in a safer place and took one look at the diagram pasted to the bottom and immediately realized my mistake. It's like you wrote,"Sometimes people see..." Man, oh man, is my face red!
Life is certainly a humbling experience at times, and this counts as one of those times. I'll let you know how I make out after I DO IT THE RIGHT WAY.
Thanks again, Terry and Mike.

Thanks, Don. I'll check it out. My URM has to be cranked up to near maximum to put out a readable wave form. I re-capped much of it this past winter but spring came and chores around the house took priority, as they do every year.
I'll attempt to work on it this winter but I have other projects backed up so the URM will have to wait its turn.
I read where someone called working on the URM "tedious." To me, that was an understatement. Man, are those components packed in there, like sardines in a can or worse.
Happy hamming to you, Don.

If you can find a BS-8 cheap, get it, because it just adds eye candy to your SM-220 but I wouldn't spend big money for one today. It's just not that good as a panadapter. I've had my SM-220 for over 30 years and for the last 25 years only used it to monitor my transmitted signal.

Charlie:

Sometimes these manuals are just not very well human factored. You wont be the last to make this mistake. No harm done as you will have to adjust the slug you was trying to tune eventually in the sequence.

Yes we would like to hear how it goes.

I agree with Pete. Before you go this route take a look at the L-pan model on their website. The new IQ/SDR panadapters are getting to be very popular. Much better performer than the Kenwoods. Can read reviews on Eham and see some demos on You Tube. Suggest also look at Jan N8CBX QRZ page and email him. He has SDR panadapter mated with his TS-820. I think if I was to buy today I would get the L-pan unit.

The fix is in place. R15 was the culprit. If it ever fails again I'll switch to a different type resistor.

--- In TS-520_820_530_830@yahoogroups.com, "David L" <dlacroix@...> wrote:
>
> Many thx for the info Gordon. I checked R15 as you suggested. It looked totally normal. Then I tested it with ohmmeter in circuit and it seemed a little squirrelly. So I powered up and checked voltages. SG2 on one side of R15 had plenty of voltage. The other side of R15 was zero volts. So I pulled R15 out of the board and sure enough it's open. I'm short on resistors and went to the local radio shack..No luck. Will have to wait until Monday to get that 56K resistor and will update then.

Many thanks for your opinions about BS-8 unit.

I understand that is difficult to obtain one of this units in these days, but there is no problem. I supposed also that not was very usefull, only a "decorative" accesory for the SM-220.

I will take a look at the video that Terry mentioned in your message.

Again, many thanks for all.

Best for everyone.

David, EC4ACH.

David,

I have several of the SM220's and only one with BS8, if it had good sensitivity would be great. I look at it as something just to say I have a complete station. go with the recommendations of the others and get a good add-on panoramic display

Subject: [TS-520_820_530_830] Looking for a Kenwood BS-8 panadaptor.

Hi all,

I am looking for a BS-8 panadaptor unit to install into the SM-220 that I located here in Spain, because it doesn't equipped with this unit.

I would like to know also the opinion of the members of the Group that have installed this optional unit into your SM-220 and it's useful or only is a "toy".

Many thanks in advance for everything.

Best 73 de David, EC4ACH.

I totally agree. Since this is the Instruction Manual and not the Service Manual it would be more constructive to include more basic directions for the novice technician. Well, after all, this is technical hobby and it does require a larger measure of mental effort than most hobbies around these days. I'm not lazy and I'm not stupid and I do love to learn so this hobby is most rewarding to me.
Hopefully, some other "gifted" individual will read this message and not make the same mistake as I did.
I'll respond with my post-alignment comments as soon as I finish the task. It should be today, sometime, I hope.

Charlie:

There was no inference that you were stupid at all?

I was trying to say that the Kenwood documentation could be better and often contributes to confusion and mistakes. By human factoring I am saying there is a art and science to writing good instructions to make them user friendly and reduce the chance of human error. I always like it when a caution statement or note comes after the step!

Sometimes working from reproduction copies complicates things too especially looking at diagrams and photos/images that are dark or blurred.

I am delighted that you recognize that maintaining your own Kenwood hybrid takes a modicum of knowledge and experience and the desire to learn.

Terry, honestly, I didn't take it that way. That's just a modified saying that I often use. The actual version is, "I not lazy, I'm not stupid, and I'm not afraid to take a chance." I just tweaked it a little to suit this particular little adventure.
Here's my update: The alignment procedure works and the rig had drifted a little so an update was warranted; however, the 14MHz coils were not cooperating and I broke off the tip (2 actually) of the adjustment tool trying to coax movement from the coil slug. I'll order more tools, several, try a little more lubricant and move on down the line and do want I can before I finish the alignment. I think that oiling of the fan comes next and then maybe some Deoxit in the pots and on the switches while I wait for my new batch of alignment tools.
Thanks again for your help, Terry.
Until next time...

Ok I miss read what you were saying.

Better to break off a tip of plastic alignment tool than to crack the core or rip it off its mounts. You can try heating core with tip of a soldering iron with small tip. If you are breaking off alignment tools then the core sounds like it is frozen to me.

This is the sort of thing Mike was cautioning about with these old rigs. Need to be aware there is potential to induce new faults. Hopefully a little prep can prevent this. I have had success applying small drop of WD-40 at top edge of cores with a tooth pick so it runs down around the circumference between core and former.

I am not sure what you mean by rig drifted some? If you are talking about frequency drift you are not affecting that with coil pack alignment. That is typically due to 9VDC regulator problem or a problem on the VFO board. There is a warm up drift spec and a post warm up drift spec in your manual. Should be able to meet and exceed those specs. If frequency is jumping as you turn the VFO or has dead spots then the VFO air variable capacitor rotor shaft wiper contact is likely dirty and will need good cleaning.

Make sure you set the Het Osc coils on the slow side of the response curve slope. If you are doing this by ear or with RF probe/VTVM if you set RF voltage peak approaching from the fast side of the response curve the oscillator may not start each time you switch to that band.

Lastly it is not likely that you cant simply try to get oil into the lube holes unless you have some form of hypodermic oiler. I like to remove fan rotor so can get good access to the bushing holders. These have felt wicks in them that are typically all dried out. The small screws that hold the motor and fan together and the fan blade on the shaft have thread sealant on them. I heat the screws with soldering iron and they usually turn easily then. Just make sure you get orientation correct on re-assembly so the lube holes point up. With bushing holders laying flat can now give them a good soak to wick up the oil. After reassembly I let fan sit on paper towel to catch any excess oil. Once you do this method you should be able to get some oil in the small lube holes if you lube the fan once a year. If the felts are ever allowed to dry out then may have to disassemble and re-saturate.

That's an interesting tip, Terry. I might try that or I might just let the slugs remain as they were. I don't want to create a problem for myself. "If it ain't broke..." right? I generally work 20 meters and she was purring along nicely without my fumbling around.
By, "drift," I meant that turning the first few cores that I turned resulted in an increase in the S-meter reading and that probably age has taken it's toll on the previous alignment and she "drifted" a little. Obtaining maximum reading is the desired result per the manual, so this is progress.
Also, thanks for the tip about the fan. I do have a clock oiler that use for these sort of things. The long needle-like probe that distributes the oil is just wonderful in those hard to get places. Perhaps it will work in this case? We shall see.
One last goodie. I recently purchase a TS-520S "parts only" bench queen so that I can obtain parts, such as coil slugs, when and if the need arises. Something tells me that was a wise move on my part. The bench queen arrived with a 20 amp fuse installed where the 2 amp fuse should be and it would appear, due to the melted insulation on numerous wires, that this same technician (?) used a super-heated piece of rebar to remove some components from the RF Unit board. It's quite a sight under the hood.
As always, thank you, Terry.

Hi to all
During calibration bpf-a for ts-830 , step 10, page 35, service manual,
i was taken off the sweep generator from the one who had lent me;
(he informed me that he sold it for discontinued business !)

at this point I'm stuck and the only things available are a signal generator up to 30/35 MHz and an oscilloscope to 40 Mhz
can anyone suggest a procedure to try to end the calibration with alternative method ?

now , the display of VFO, is on when frequencies are from 7.3 to 7.5 MHz, about ; outside of these frequencies the display off!
(i not attempted for others bands)
the components touched are T13,T14,T15

Ugo

Ugo:

I sent a response earlier but it has not shown up? You really need a Sweep Gen with Kenwood markers to be able do do the stagger tuning you need to do.

However, that being said. You can do the old fashioned method using a regular RF sig gen and a RV millivolt meter or O-scope and inject 50khz to 100 khz steps at VFO signal input on PLL board and then measure the RF voltage levels at the Emitter of buffer amp Q35. You make yourself a table of frequency vs rf output voltage and then plot the points on a graph paper. Before I got a good Sweep gen I use to plot the points using Excel. When you get close to Fc (5.750mhz) best to use smaller frequency steps and take more points. This method has been used for many years by hams to sweep all kinds of filters and you will get a nice graph of the frequency response curve as you have left the filter adjustments.

I would use a Freq Counter on the output of your RF sig gen unless it has good calibrated output. Also important the your RF sig gen output level does not vary as you change the frequency.

For your first pass can just slowly sweep the RF Sig gen from 5.000mhz to 6.100mhz and find the peak and just add 8.830 to what you read on your freq counter. It should be very close to 14.580 if someone hasnt messed with the adjustments.

Problem is this manual stepped graph paper method is not very good for making adjustments. It can take many repeat cycles to see the results of your adjustments and the three adjustments interact. Usually I adjust for Fc first.

So much easier to have Sweep gen with Hybrid markers and watch your changes on the O-scope in real time as you adjust.

You dont need a 35mhz or 40mhz sweep or rf sig gen. For BPF-A you will inject 5mhz to 6mhz and for BPF-B and BPF-C you will inject 14.0mhz to 15.5mhz. There is a mixing scheme involved. For BPF-A Step 10 you are lifting the VFO signal to the PLL and substituting your RF sig gen from about 5.000mhz to 6.500mhz. I would use a frequency counter to make sure you know what the actual frequency of your rf sig generator is. Set sig gen level to 0dBm or 224mv.

You should see peaks in rf output voltage level at Q35 emitter at Fcl (5.400Mhz), Fc(5.750mhz), and Fch (6.100mhz). Fcl and Fch are the 3dB roll off points of the filter. Filter should be approx 700khz wide. With 224mv of 5.750mhz injected you should see approx 160mv output at emitter of Q35 which corresponds to 14.580mhz Fc.

Just make sure you have the bandswitch matrix disabled and you have 9vdc bias applied to filter switching diodes as you proceed to next filters. Service manual instructions could be better. I started revising and never finished the project.

I use a micro grabber test lead to get on emitter of Q35. You may have to gently move L21, C114, and R45 to get test lead on it.

I forgot to ask before you attempted sweeping the PLL BPFs was your digital display accurate?

Have you checked the accuracy of the PLL 10mhz clock? If not go to TP-2 and connect your Freq Counter (assumes calibrated freq counter) and measure and if off adjust using trimmer cap TC-1.

Also go to CON output and measure 0.5-1.0mhz out as you vary the VFO thru range.

Hi Terry
thank you for response and alternative method !

I apologize if i have not seen an answer exists that could help me but I have some problem with English (as you can see from the way I write) and did not know how formulate the question in the search;

Your answer and the method that at this point becomes the only solution possible for my situation;

This night I had temporarily resolved the problem by going in different bands, and varying slightly t14 t13 t15 I did reappear in the display pointing to the frequency limits min and max of each band: Of course not 'a solution but at least I have a starting point min (i attempted a QSO with french om and i received S5-9 :-)

Regarding Emitter of Q35 I used in hook with small wire with a stiff end, of those used for the experimental breadboards (Arduino ecc....), which hook remains far from the other terminals of the transistor and that this may 'be locked to the frame of the apparatus with tape (i used same system for check anchor point at position not good)

Well let's see what I can do by following your advice

i'll let you know

Ugo

Ugo: OK dont worry about your English. If you need more help or do not understand what I have written just come back and ask.   I never advise anyone to attempt to adjust any KW hybrid BPFs if they do not have a Sweep Gen. Can always do the old manual method with RF sig gen and plot the as found response curve on graph paper, but almost impossible to properly stagger tune the 3 resonant circuits with this method. TS-520 has couple of BPF and for life of me cannot figure out way people mess with the slugs on these. If you just want to see where they are set then a RF sig gen and RF probe/VTVM and injecting steps and recording the RF output voltage and then plotting the points is a fun exercise to show the response curve, but it will be a frustrating exercise if you then need to adjust and run another stepped "sweep". Maybe you can find someone close to you that will have a RF sweep gen that you can borrow? Terry K9TW --- In ts-520_820_530_830@yahoogroups.com, <vierugo@...> wrote: Hi Terry
thank you for response and alternative method !

I apologize if i have not seen an answer exists that could help me but I have some problem with English (as you can see from the way I write) and did not know how formulate the question in the search;

Your answer and the method that at this point becomes the only solution possible for my situation;

This night I had temporarily resolved the problem by going in different bands, and varying slightly t14 t13 t15 I did reappear in the display pointing to the frequency limits min and max of each band: Of course not 'a solution but at least I have a starting point min (i attempted a QSO with french om and i received S5-9 :-)

Regarding Emitter of Q35 I used in hook with small wire with a stiff end, of those used for the experimental breadboards (Arduino ecc....), which hook remains far from the other terminals of the transistor and that this may 'be locked to the frame of the apparatus with tape (i used same system for check anchor point at position not good)

Well let's see what I can do by following your advice

i'll let you know

Ugo

> I sent a response earlier but it has not shown up? You really need a Sweep Gen with Kenwood markers to be able do do the stagger tuning you need to do.
>
> However, that being said. You can do the old fashioned method using a regular RF sig gen and a RV millivolt meter or O-scope and inject 50khz to 100 khz steps at VFO signal

input on PLL board and then measure the RF voltage levels at the Emitter of buffer amp Q35. You make yourself a table of frequency vs rf output voltage and then plot the points on a graph paper. Before I got a good Sweep gen I use to plot the points using Excel. When you get close to Fc (5.750mhz) best to use smaller frequency steps and take more points. This method has been used for many years by hams to sweep all kinds of filters and you will get a nice graph of the frequency response curve as you have left the filter adjustments.

As I am about to set up my shack(spare bdrm) on the other side of the house from the mains ground rod. I am confused by the statement below. Do I keep all shack/ antenna grounds separate from mains grnd or do I join shack/Ant grnds to mains rod in parallel??? Any clarification would greatly be appreciated. (I noted the parts that confuse me) This was excerpted from another site Replacing of the old 2-wire line cords on our rigs with 3 wire grounded cords? Surprisingly, not a good idea. In fact, many electrical codes around the country would frown on it. The reason is that it is expected the ONLY ground on the house wiring to exist at the service entrance. Adding additional grounds at points perhaps on the other side of the house could produce ground loops, unexpected ground current flows, and unpredictable ground potentials .   Because your Amateur equipment has its own ground system (or SHOULD), they do not want you to connect it to the primary service ground . Stick with a 2-wire line cord and the best local ground system you can attach to your gear. Thanks, Jerry K4GEW

Jerry,

Good rule of thumb from my past experience and from when designing and making HTC cables is your radio ground, tower ground and common house ground should all be connected, (bonded together). Subject to soil conductivity, the first 5 feet of the ground rod is the most important. As I have ground water at 6 feet, I installed 3x 8ft earth stakes on my tower (one per leg), outside my radio shack 3x earth stakes 5 feet apart. Then bonded back to the house earth system (240v system) which is then bonded to my copper water pipes (VK standards) Hope that helps, if you need we can discuss all the jargon abt when how and why.

Also, if electrical codes frown on replacing the 2-wire electrical cord
and plug, especially a non-polarized 2-wire plug, with a 3-wire cord
(including the safety ground), why are all appliances, PCs, printers,
and high-end consumer electronics include a 3-wire (grounded) plug?

Not grounding the two together, the station ground and the service ground can create a ground potential difference and a better chance to attract that dreaded beast a lighting strike.

Possibly because of the increased levels of non-conductive material used in devices that no longer allow for efficient internal grounding. Case in point, here in NJ the grounding spec has shifted from cold water pipes to gas pipes because of increased use of PVC products in the former. -O'B. ex-KA2MKI --- In ts-520_820_530_830@yahoogroups.com, <amfone20000@...> wrote: Not grounding the two together, the station ground and the service ground can create a ground potential difference and a better chance to attract that dreaded beast a lighting strike.

Hi do any members of the group have experience with the TS-830M . My question is ,is it possible to fit (or has any one done it) the cw narrow filter YK-88C . There is no position beause the AM filter takes the space of the optional CW filter . Did Kenwood make a special IF board for this AM version or did they modify the existing board . Would i have to make a small board with both SSB and CW filters on it with relay switching , or is there an easier to achieve what i want a 500hz CW filter

Cable to connect kenwood TS 820 S to HeathKit SB 200
I need some help building the interface cable
I have the 8 pin remote connector. I have the Kenwood TS820s manual and have looked at page 37 Fig 30.

Can some one explain this cable build in simple terms?

I guess as I get older I am getting more brain dead.

Thanks to all.

Topic: 44350 Message: 44350

I have a TS-511 and am having problems getting the 500Hz CW filter installed and working correctly. I have it installed and I get no receive the way it is. So am wondering is there something I need to do besides install the filter and go to the CW position. There is no mention of anything in the manual about installing it. However, there are two small jumpers on either side of the filter on the IF board that look like they might need to be removed...Does anyone know anything about the TS-511 it is an oldie. Steve NU0P

Andy,

Be forewarned, the SB-200 relay voltage is -120VDC!!! Harbach sells a "Soft Key" ($27) mod for the SB-200. If that mod has not been installed in your SB-200 then I highly recommend you purchase and install it in your SB-200. See the following link for details on the Soft Key mod:

http://harbachelectronics.com/main/page_products_sb200__sb201.html

The 8 pin remote socket is used to control a linear amplifier's relay. You will need the following plugs

1. RCA male
2. 8 octal male
3. 2 lengths of shielded cable, one for the relay and one for the ALC

The relay connection is made by connecting the center conductor on one end to pin 5 and the shield to pin 1 on the 820's 8 pin octal plug. Connect the other end of the same shielded cable, center conductor to the center pin of the RCA male plug and the shield to the outer ring of the RCA plug.
Mark this RCA plug as "RELAY"

The ALC connection is made by connecting the center conductor of the other shielded cable to pin 6 and the shield to 4 on the 8 pin octal plug. Connect the other end of the second shielded cable, center conductor to the center pin of the RCA male plug and the shield to the outer ring of the RCA plug.
Mark this RCA plug as "ALC".

That's all there is to the RELAY and ALC connections.

Plug the "ALC" RCA plug into the SB-200's "ALC" socket and the "RELAY" RCA plug into the SB-200's "RELAY" socket then plug the 8 pin octal plug in the TS-820's 8 pin REMOTE socket.

Connect a short length of coax cable, RG-8x is fine, between the TS-820's rear SO-239 and the SB-200's SO-239 "INPUT" socket. The SB-200's OUTPUT socket connects to the antenna, SWR meter, tuner, etc.

If you do not have the SB-200 manual, purchase it then read the operation section thoroughly until you understand how to safely and properly use the amplifier before attempting to operate the SB-200.

Andy,

I failed to indicate how many RCA male plugs you will need. Purchase at least 4 RCA male plugs. You can purchase them at Radio Shack in a 4 pack under part number 274-319 for $3.49.

Radio Shack sells a 6 foot shielded cable with an RCA male plug on one end and stripped and tinned wires on the other end under part number 42-2371 for $6.49 "each". You would need 2 of these to make the connections between the TS-820's 8 pin octal plug and the SB-200's RELAY and ALC sockets.

> This is the sort of thing Mike was cautioning about with these old rigs. Need to be aware there is potential to induce new faults. Hopefully a little prep can prevent this. I have had success applying small drop of WD-40 at top edge of cores with a tooth pick so it runs down around the circumference between core and former.

Just to wrap up this particular issue, the new alignment tools arrived yesterday. I ordered them on the 28th and they got here on the 30th. Amazing! Ken Kemski (ken@...), as always, does a fantastic job filling his orders.
Anyway, that last drop of oil that I added to the 14MHz coils did the trick and the slugs are now adjustable and I've completed the alignment. My rig is operational again.
Now on to the next little adventure.

My brain is slow this morning.

The SB-200 should be operated from "240VAC" ONLY!!!

If your shack does not have 240VAC available then you will have to have
an electrician come and install a 240VAC line to your shack with the
appropriate socket. The SB-200 power plug will also have to be replaced
with a 240VAC plug.

There may be some hams who may tell you they are operating their SB-200
off of 120VAC without any problem. Do NOT follow that advice!! For
safety and reduced risk of fire from overheated house wiring, do NOT
operate your SB-200 from the 120VAC wall outlet!!!

The SB-200 will work fine on a 120VAC line if you have a dedicated 20A line "for its use only." Using it on a 120VAC branch circuit is certainly not advised - as per Mike. In my case, I use my SB-200 on a dedicated 120VAC Romex 12/3 line with a 20A breaker and a 20A 120VAC outlet, and the distance from the breaker box to the outlet is only 20 feet. The SB-200's maximum current draw on 120VAC line is 16A (and, 8A on a 240VAC line). If you do operate your SB-200 on 240VAC, not only do you have to change the plug, but the jumpers on Terminal Strip S underneath the SB-200 chassis. This is described on Pictorial 7 of the SB-200 manual.

Andy,

It's entirely up to you whether you operate your SB-200 on 120VACor 240VAC.

Operating the amplifier on a 120VAC 20amps circuit leaves only "4 amps"
of a "safety margin" which, in my opinion, is "insufficient"!

I certainly don't intend to "agree to disagree" here, but I've never observed a 16A line current peak using my SB-200 on my dedicated 120VAC line. The maximum 16A line current spec @ 120VAC comes from the specifications page of the SB-200 manual. If you're planning to run the SB-200 on SSB, the maximum line voltage current will only occur in very short transient periods. Mike is correct that the SB-200 works _best_ off of 240VAC (as with practically all linears, including the Elecraft KPA500 and Ameritron AL-811 and ALS-600), but if that was technically the only operational voltage option for the SB-200... why did Heathkit NOT supply the SB-200 with a proper 240VAC line cord and plug. Rather, they supplied the kit with a standard 120VAC line cord with a grounded 120VAC plug. Heathkit plainly advertised the SB-200 as either 120VAC or 240VAC capable.

It would be interesting to take a poll of SB-200/SB-201 owners on this. It's my feeling that a majority of SB-200s are connected to a 120VAC line... hopefully, not on a shared branch circuit.

However, if you were planning to run the SB-200 on one outlet of a 120VAC branch circuit, especially if the same circuit supplies 120VAC to your TS-820S, DON"T DO IT! I would strongly suggest you to run a dedicated line for the SB-200. If you are paying for a dedicated line to the shack, go ahead with the 240VAC installation instead. It won't cost you much more, as labor is the majority of the installation expense.

I'm in deep trouble now. I've been running all my stuff, including my SB-200(and several other linears over the years), off one 120VAC line for the last 45 years.

Topic: 44355 Message: 44361

Well I did that also, never giving special thought to the current
draw. For years I ran my SB-220 on a 220 line so that was no problem
but recently after 20 years off the air I set up an SB-201 and was
running both on the same circuit. After bringing this to my
attention, I found that two receptacles 8 feet apart were on separate
20 amp circuits. So, looks like the 820 gets a new power location. I
think it is a good idea just from the voltage drop possibility and
safety to run them on separate circuits if possible. I like 220 volts
if it can be done reasonably but for me it would require a long
difficult run so yes, nice to have but not a big compromise. I also
look at the little power cord from the back of the 820 and wonder if it
could carry 16 amps.

So another thought, anyone have a feel for what the market might be
for some new KB1 knobs?

I used "clock oiler" and that's what I generally rely on for any hard to get at objects that require lubrication. A clock oiler has a 3-4 inch long needle-like probe attached to the oil supply and that provides a method to apply oil in tight quarters.
I'm not sure of the specific composition of the oil itself but I believe it to be a light machine oil. I applied one small drop, let it wait for 24 hours, and then attempted to turn the slug. When that failed I simply repeated the process while being cautious not to over-oil the slug and end up shorting out a component somewhere.
I never had to resort to Terry's tip about heating the slug so that little trick will have to wait for another time.

Topic: 44338 Message: 44363

Thanks to all responders. I feel good about what I plan now and will follow the advise of bonding all ground rods together to the service entrance ground after grounding the TS830s and it's other components together in the shack at their respective ground lugs on the back of each unit. This is without a doubt the VERY best place to come if you own any of these really neat old radios. Thanks again, Jerry K4gew --- In ts-520_820_530_830@yahoogroups.com, <hardedge@...> wrote: Possibly because of the increased levels of non-conductive material used in devices that no longer allow for efficient internal grounding. Case in point, here in NJ the grounding spec has shifted from cold water pipes to gas pipes because of increased use of PVC products in the former. -O'B. ex-KA2MKI --- In ts-520_820_530_830@yahoogroups.com , <amfone20000@...> wrote: Not grounding the two together, the station ground and the service ground can create a ground potential difference and a better chance to attract that dreaded beast a lighting strike.

Station ground and electrical service (service entrance) ground should
be bonded together - not isolated.

See this link. It's probably more info than you'll ever need, but a
very good treatise on station grounding.

http://www.w8ji.com/station_ground.htm

Don W9CW

Also, if electrical codes frown on replacing the 2-wire electrical cord
and plug, especially a non-polarized 2-wire plug, with a 3-wire cord
(including the safety ground), why are all appliances, PCs, printers,
and high-end consumer electronics include a 3-wire (grounded) plug?

Topic: 44364 Message: 44364

does anyone have an old rf board that i could get the vr-2 off of or does anyone have one in a parts bin ? i am in need of one or two plz let me know!!! thanks Ron KK4PWF

44365. Kenwood HF Net Weekly Update for September 1, 2013

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-01 18:39:29 UTC
From: <mgilger@...>
Topic: 44365 Message: 44365

The Saturday's net on 40 meter we had 22 stations checking in under good band conditions. There were 6 new stations checking in, KD4GIX, K2MA, KD8OWH, KA1HIR, KC9SQC, and K2LDM. Out of all the check ins, there was: 3 running TS-520(x)

2 running TS-530(x)

2 running TS-820(x)

3 running TS-830S

0 running TS-900

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday’s net on 20 meter we had 7 stations checking in under good band conditions. Out of those, there was:

2 running TS-520(x)

1 running TS-530(x)

1 running TS-820(x)

2 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940’s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to

make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:

http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 – Oct. 2012
Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday’s, net total = 47, Sundays total = 20

December 2012, Saturday’s, net total = 74, Sunday’s total = 70

January 2013, Saturday’s, net total = 93, Sunday’s total = 87

February 2013, Saturday’s net total = 103, Sundays total = 87

March 2013, Saturday’s, net total = 112, Sunday’s total =39

April 2013, Saturday’s net total = 52, Sunday’s total = 29

May 2013, Saturday’s net total = 45, Sunday’s total = 50

June 2013, Saturday’s net total = 30, Sunday’s total = 27

July 2013, Saturday’s net total = 63, Sunday’s total = 41

August 2013, Saturday’s net total = 82, Sunday’s total = 50 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Ron: I think you have a typo. If the VR-2 you need is the span pot (to set S9) for the TS820 S-meter it is a vertical lead 500k ohm pot on the IF board and not the RF board.   If no one has a TS-820 IF board that they are willing to harvest parts from (which would be best for you) then take a look on Ebay and see if you can find a miniature vertical mount substitute. Best if it is vertical mount style. If I am confused about what you need please disregard this response. I am going by what I understood you to say last time we talked. Ron: No problem. I dont have a TS-820 board that I could harvest a VR-2 from. Hopefully some one else will. If not then suggest you try Ebay for a sub and also ask Bob Mansker what he gets for a good TS-820 board. You could then swap boards and keep your original board for a parts board. Hate to make a parts board out of it if all you need is VR-2. Of course could also look for a "tech special" TS-820 if you have good credit at bank and can get a 2nd mortgage! 44369. excessive loss through CW filter

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-02 14:10:33 UTC
From: Craig Roberts
Topic: 44355 Message: 44369

I have installed Trio/Kenwood YK-88C filters in both my TS-830S and TS-530S with varying results.

The 830 appears to act normally with some attenuation of the incoming CW signals but nothing abnormal. On the 530, however, the passband with the filter in seems very narrow and the signals knocked down to almost oblivion unless unless centered absolutely precisely. Even then, they are noticeably weaker than on the 830.

I must say that the 530 sounds terrific on strong signals with the filter in since atmospheric noise is totally eliminated, but weak signal reception is greatly compromised.

Watcha think?

Thanks and 73,

Craig

44370. TS-830S freq display anomaly

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-02 14:54:38 UTC
From: Craig Roberts
Topic: 44355 Message: 44370

Oh -- and then there's that last little annoyance left on my TS-830S.
The display reads high by about 100 - 200 Hz. And, that's with the
trimmer dedicated to correcting such things at its limit. In other
words, the "lowest" display reading it will set is still about 150 Hz
higher than the actual frequency.

This by the way, has been determined by comparing the display with my
TS-530S which was just carefully and accurately aligned by one of our
fully equipped gurus (who lives 2,800 miles away).

Since nothing more than an ancient VTVM and a DVM comprise my test bench
at the moment, I am at a distinct disadvantage when it comes to
servicing my otherwise perfectly functioning 830.

Any "quick and dirty" (but not too dirty) ideas?

Many thanks,

Craig
W3CRR

Subject: [TS-520_820_530_830] RE: vr-2

Ron: I think you have a typo. If the VR-2 you need is the span pot (to set S9) for the TS820 S-meter it is a vertical lead 500k ohm pot on the IF board and not the RF board.   If no one has a TS-820 IF board that they are willing to harvest parts from (which would be best for you) then take a look on Ebay and see if you can find a miniature vertical mount substitute. Best if it is vertical mount style. If I am confused about what you need please disregard this response. I am going by what I understood you to say last time we talked. 44372. Source problem???

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-03 03:05:39 UTC
From: W5RKL
Topic: 44372 Message: 44372

Here's a problem for the inexperienced hams to solve. This is NOT a made up problem, this problem actually occurred in my Heathkit SB-100. I know this is not a Kenwood hybrid but it is a good problem to solve for those studying vacuum tube theory.

Remember all those times you were told to take voltage measurements? Well this is where all that comes "pays off"!!!

Symptom:
Receive audio is distorted
The S meter, after 3 to 4 minutes warm up, drifts below zero and remains pegged hard against the meter peg
No signal, calibrator or strong receive signal brings the S meter above zero

Initial checks:
Meter zero pot is adjusted but no change, meter remains pegged below zero
Detuning the Preselector results in no change in the symptoms except the audio level is lower
Adjusting the RF Gain control CCW causes the S meter to rise above zero and when set fully CCW the meter pegs fully to the right.

Voltages were check for the receiver RF amp, receiver first mixer, first and second IF amplifiers. All 4 stages are directly or indirectly through resistors, connected to the same common receiver's AGC buss.

The following voltage measurements were taken and the results are as follows:

Receiver RF Amp and first receiver mixer's plate and screen voltages are good when compared to the manual's voltage chart
Receiver RF amp and first receiver mixer's grid voltages have decreased by .2VDC less than the voltage chart levels

First IF amplifier's plate and screen voltages were found to be significantly lower than the manual's voltage chart
First IF amplifier's grid voltage was found to be +1.5VDC

Second IF amplifier's plate and screen voltage were found to be lower than the manual's voltage chart
Second IF amplifier's grid voltage was +.8VDC

With all this information, what is the exact source of the problem?

Don't guess, use the information provided to solve the exact source of the problem then explain steps taken to fix all the problems.

Your choices are

1. Loss of operating bias to all 4 stages
2. First IF amp grid resistor had significantly increased in resistance value
3. RF gain control is very dirty resulting in improper operationg
4. Bias supply's filter capacitor has failed resulting in AC ripple on the bias buss
5. One of the tubes is gassy
6. Audio tube has a grid to screen short
7. Bad meter zero pot

Hi Terry
ok, so if I write something outrageous are justified :-)

In step 10 of calibration should therefore be made as follows:

1) disconnect connector 1 in pll board
2) disconnect connector 5 in pll board
3) connect cathode d24 with jumper wire to R44
4) connect local rf generator input fq meter (for read frequency)
5) connect out fq meter (RF signal) connector to rear, ext VFO-
6) connect a wire from emitter to Q35 volmeter scaled to millivolts
7) normalize out from RF to 224 mV

start your procedures with T14, T15, T13

one's question:

T14 is Fc (central)
T15 is Fh
T13 is Fl

is correct or i swap T15 and T13

Ciao
Ugo

You can do the old fashioned method using a regular RF sig gen and a RV millivolt meter or O-scope and inject 50khz to 100 khz steps at VFO signal input on PLL board and then measure the RF voltage levels at the Emitter of buffer amp Q35. You make yourself a table of frequency vs rf output voltage and then plot the points on a graph paper. Before I got a good Sweep gen I use to plot the points using Excel. When you get close to Fc (5.750mhz) best to use smaller frequency steps and take more points. This method has been used for many years by hams to sweep all kinds of filters and you will get a nice graph of the frequency response curve as you have left the filter adjustments.

6mhz and for BPF-B and BPF-C you will inject 14.0mhz to 15.5mhz. There is a mixing scheme involved. For BPF-A Step 10 you are lifting the VFO signal to the PLL and substituting your RF sig gen from about 5.000mhz to 6.500mhz. I would use a frequency counter to make sure you know what the actual frequency of your rf sig generator is. Set sig gen level to 0dBm or 224mv.

Ugo:
I would just connect the RF sig gen output signal to PLL board Conn 6 Pin 1 but you can connect at Ext VFO if you want.
Using a Sweep Gen with Kenwood markers and O-scope I typically would first adjust the series resonator T14 for a peak very near 5.750mz (14.580mz) which is Fc (Center frequency) .
I then adjust the parallel resonators for equal roll off which should occur at 5.400mhz(14.230mhz) and at 6.100mhz (14.930mhz). These interact so have to go back and forth to get as close as possible. Basically with a Sweep gen and marker signals you just adjust all three filter elements to match the frequency response curve shown in the service manual.as close as you can and dont concern yourself about the rf output voltage levels from Q35. The response curves are fairly symmetrical.
However from my notes I do find some Q5 emitter rf voltage levels for the corresponding frequencies of Fc, Fh, and Fl.

Perhaps you can use these levels for you standard RF sig gen method of tuning the BPF resonators?
Here is what I have:
Fc (Center) usually occurs close to 160mv. Fl (Low) close to 130mv and Fh (High) close to 120mv. So if you assume roll off occurs from 120mv to 130mv then can use those levels as starting points for adjusment of the two parallel resonators. You may be able to see as you swing your sig gen frequency up or down from FC when the rate of change is getting steeper?
If I was to try adjusting them without a Sweep Gen. I would start with the series resonator T14 and adjust if for a peak output rf voltage at Q35 emitter with 5.750mhz @224mv from the RF sig gen injected .
I guess then would swing the RF sig gen freq down from Fc until see the rate of RF voltage fall getting steeper and note that freq.Then would go back to Fc and swing RF sig gen freq up from FC until see rate of rf voltage fall getting steeper and note that freq. See if this occurs close to 120 to 130mv. .
Based on the levels I noted above I think would adjust T15 for Fh and T13 for Fl and set them for an output level of approx 120 to 130 mv if I was unable to see where the rate of change gets faster.
I suspect just adjusting T15 and T13 for approx 120mv to 140 mv level is about as good as you will be able to do.
you can then run a manual stepped sweep again and plot on graph paper and compare to the response curve in the Service Manual. If you get FC close to 5.750mhz and 160mv I would not mess with T14 anymore.
Terry K9TW. . . . .

44375. Vacuum tube theory videos

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-03 20:09:32 UTC
From: W5RKL
Topic: 44375 Message: 44375

I made a couple of short videos showing what happens to the Grid, Cathode, and Screen voltage of a simple amplifier circuit (IF amp in this case) when grid voltage changes by the application of AGC voltage based on the strength of a receive signal. The videos are of the first IF stage, V3, in my Heathkit SB-100. Although the SB-100 is NOT an Kenwood hybrid, the idea behind the videos is to show basic vacuum tube concepts. The same thing applies to your hybrids final amplifier or driver tubes. As the grid voltage varies so does the gain of the tube(s) as shown in the videos. You can perform these simple test yourself but you will need a VTVM or two, the 1Meg probes for each VTVM, and take the time to experiment. If you are studying vacuum tube theory, experiments such as this can easily make what you read/studied, "make sense"!

There are 2 videos, one shows the variations in cathode voltage along with grid voltage (AGC voltage) and the other shows the variations in grid and screen voltage.
\
Both videos begin with the tube operating at maximum gain. As the signal is applied, AGC voltage is produced that is applied to the grid of the tube resulting in a "reduction" in the tube's gain. When the gain is reduced the grid voltage increases (combination of fixed operating bias and AGC voltage), the Cathode voltage decreases due to reduced electron flow in the tube, and the Screen voltage increases due to a reduced voltage drop in the screen circuit. The opposite occurs when the gain is "increased" caused by the reduction in the strength of the receive signal.

If you all remember the many times we have said the importance of measuring voltages, this is a clear example of what we are talking about!

If you are interested in seeing the videos drop me a private email and I'll send them to you. Each video is "10meg" so your Internet service provider/email server must allow you to receive files larger than 10meg. I hope to have them uploaded to the Files section soon.

The videos can be viewed using Windows Media Player, included with all versions of Windows.

I'm working on another video to show what happens when the a tube that shares the AGC buss with another tube, turns Positive due to excessive gas. It's easy to "simulate" a gassy tube by using a 1.5VDC AA battery and applying that voltage to the grid of one tube we'll call tube "A" while monitor the grid, cathode, and screen voltage of the other tube we'll call tube "B". What do you think will happen to tube "B's" grid voltage? Also what happens to the output signal of both tube "A" and tube "B"?

Ugo:
Just a reminder. When you asked about an alternate method to check the alignment of the PLL BPF without a Sweep Gen. I suggested you could use the manual stepped method with a RF Sig gen and a RF millivolt meter or O-scope. At that time I suggested if you took enough rf output voltage data points stepping from 5.000mhz to 6.500mhz and plotted them on graph paper you would be able to see what the response curve looks like as presently adjusted.
I also mentioned that trying to align a 3 element Butterworth BPF by this method is not easy or recommended method because you cannot see in real time the effect any adjustment on any resonator makes on the response curve. It just isnt very practical.
Today in lieu of a Sweep gen and Scope tech would use Spectrum Analyzer and Tracking Gen, 2 port VNA, and/or perhaps a return loss bridge. In old days we would grid dip each resonator and squeeze turns of coils and call it good. .
I am curious if you ran an as left manual sweep and plotted the points on a graph and compared it to the response curve in the Service Manual? If so, what did you determine?
You are looking for a filter response where FC (center) is 5.750mhz (14.580mhz) and the filter is approx 700khz wide. If close to that then assuming rest of PLL is aligned properly the PLL should work fine unless you or someone else tweaked on the other two BPFs?
Terry K9TW.

I would just connect the RF sig gen output signal to PLL board Conn 6 Pin 1 but you can connect at Ext VFO if you want.

Using a Sweep Gen with Kenwood markers and O-scope I typically would first adjust the series resonator T14 for a peak very near 5.750mz (14.580mz) which is Fc (Center frequency) .

I then adjust the parallel resonators for equal roll off which should occur at 5.400mhz(14.230mhz) and at 6.100mhz (14.930mhz). These interact so have to go back and forth to get as close as possible. Basically with a Sweep gen and marker signals you just adjust all three filter elements to match the frequency response curve shown in the service manual.as close as you can and dont concern yourself about the rf output voltage levels from Q35. The response curves are fairly symmetrical.

However from my notes I do find some Q5 emitter rf voltage levels for the corresponding frequencies of Fc, Fh, and Fl.

Perhaps you can use these levels for you standard RF sig gen method of tuning the BPF resonators?

Here is what I have:

Fc (Center) usually occurs close to 160mv. Fl (Low) close to 130mv and Fh (High) close to 120mv. So if you assume roll off occurs from 120mv to 130mv then can use those levels as starting points for adjusment of the two parallel resonators. You may be able to see as you swing your sig gen frequency up or down from FC when the rate of change is getting steeper?

If I was to try adjusting them without a Sweep Gen. I would start with the series resonator T14 and adjust if for a peak output rf voltage at Q35 emitter with 5.750mhz @224mv from the RF sig gen injected .

I guess then would swing the RF sig gen freq down from Fc until see the rate of RF voltage fall getting steeper and note that freq.Then would go back to Fc and swing RF sig gen freq up from FC until see rate of rf voltage fall getting steeper and note that freq. See if this occurs close to 120 to 130mv. .

Based on the levels I noted above I think would adjust T15 for Fh and T13 for Fl and set them for an output level of approx 120 to 130 mv if I was unable to see where the rate of change gets faster.

I suspect just adjusting T15 and T13 for approx 120mv to 140 mv level is about as good as you will be able to do.

you can then run a manual stepped sweep again and plot on graph paper and compare to the response curve in the Service Manual. If you get FC close to 5.750mhz and 160mv I would not mess with T14 anymore.

Terry K9TW. . . . .

Hi Terry

ok, so if I write something outrageous are justified :-)

In step 10 of calibration should therefore be made â□□â□□as follows:

1) disconnect connector 1 in pll board

2) disconnect connector 5 in pll board

3) connect cathode d24 with jumper wire to R44

4) connect local rf generator input fq meter (for read frequency)

5) connect out fq meter (RF signal) connector to rear, ext VFO-

6) connect a wire from emitter to Q35 volmeter scaled to millivolts

7) normalize out from RF to 224 mV

start your procedures with T14, T15, T13

one's question:

T14 is Fc (central)

T15 is Fh

T13 is Fl

is correct or i swap T15 and T13

Ciao

Ugo

Andy,

You will have to get another connector OR re-wire your 120volt one. The wiring scheme for 12(13.8vdc) is shown on page 7 of the "operating manual," Fig 1b

You have to get another Jones Plug & wire it up (in manual)...
Your CW power on 12 volts will be less than on 120 AC...
I have sold several DS-1A converters..
Happy solder smoke in your eyes.. :)
Bob

Hello Terry

the problem with this is that TS-830M had been tampered with, altered, modified by the previous owner for 11 meters and power to the limit:
-some of the cables in the back were almost charred and I do not know 'how did I conduct
-coils and transformers for the various ranges, apart from the 11 meters, seemed turn at random and the power transformer is not 'original which ones (some power supplies are lower: I 700 V not 800 for example ....!)
-the resistors of both the rectifier is in the final stage had been put in parallel to obtain values similar to the original ones, but with Watt > 2 and value alterated which is absolutely wrong
-the power tubes are the 6146b and the other the 6156w while the other valve is not the original one (the initial part of the code almost unreadable, and is not the correct one)
-capacitors and discharge resistors on the two electrolytic 100 uF, 500V are dropped ,eliminated, and you know how dangerous such a choice!
..... etc. etc.

Unfortunately I had the bad idea to buy online trusting of what is said by the seller and I was wrong

at this point or gave fire to everything or tried to put it back in the running:
I chose the second way:
- I cleaned all the contacts
- I replaced the cables charred (including some high voltage wires close to the chassis)
- I restored the inductance of 6.8 uH in the final stage and from 0.01 uF capacitor
(I have not found the capacitor 1nF class 1, although I would try what I 10Kv 1 nF)
- I replace all electrolytic capacitor in all board's (> 80 element !!!) with exception for freq board because no simple in double printed board remove components without create damage !

After I started to re-check all power and start alignment from step -1 , service manual , and since I had lent a sweep generator , when i am at step 10 , I started doing the calibration:
given that the filter was not absolutely as was apparent from the graph I tried to change T13 T14 T15 but as I said I had to return the instrument because the owner had sold and so are in a situation halfway;
I tried to go back and now I can see the display of the VFO from the bottom to the top, for each band, but BPFA is definitely out of the correct valuesR03;:
What do I have to lose in an attempt to make and do as you said previous commentary?
the two filters that follow?
no , no ..... do not touch them if I do not have a sweep, but the price is prohibitive besides the fact that I have not even a spectrum analyzer;
i dont know if BP-B BPF-C are altered , i can check but i can't touch without the sweep !

the only tools at my disposal are a frequency meter , borrow an oscilloscope, an usual digital multimeter and a grid-dip homemade

Well I hope I have answered your question.

What would you do in my place ?

this week I should start doing some measurements so you'll know how to proceed;

Ugo

(in the meantime I'm thinking if an Arduino with a varicap and a pair of D/A A/D + the gnuplot program + user program and doing what you said :
I could automate the sampling in steps of 50 or 100 khz tensions
(i can parallelize the rf capacitor with varicap varing voltage ....)
and transmit via socket [fq , voltage] in emitter from arduino to pc ; after with gnuplot reads the vector created and graph the values in a cartesian plane with a jpeg image can be view with refresh automatic (via html / user application ...) ;

This procedure in 5/10 seconds at max can give a correct picture of where are several voltage spikes ..... bah we'll see!)

44382. Meter problem with TS-520 se

Hi all I have just been given a TS-520se which had been in someones garage for several years. I took the covers off and gave it a good visual check and re seated the tubes and then connected it to a variac and gradually bought it up to full ac over a couple of days. Next was to connect it to a dummy load and try to tune it and here we met the first problem. having checked that that plate idle was correct which it was I tried to peak the drive in tune mode and the meter pegged backwards. In other words no reading, so I switched to cw and turned the carrier down to limit output and the same thing happened. The next step was to connect to a well tuned antenna and peak the drive in receive and then dip the plate very quickly in cw as it did not like the tune mode. all settings were exactly as manual. and it gave a good 100w out on 20m band. At this stage I quit until I could get Ideas from here. My technical experience is limited so I don't want to delve too far without some ideas first and being in the uk so far I have found no one local who is well up on hybrids. 7s de Mike m0mcy (recently passed) formerly 2e0mcy

44383. De-Oxit - Which type please?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

Topic: 44383 Message: 44383

Hello to the group

I have read many times in various postings here about using De-Oxit for switch contact cleaning. There appears to be several different types/grades available, and I am seeking advice please as to which is the correct one to use on the noisy bandswitch in my TS-530S.

Advice appreciated.

Many thanks

Ugo:

Yes now I understand your problem. This would be OK if owner had been honest and you got it for a very good price knowing it would require a lot of work. Well any time any of us buy a Hybrid site unseen it is a risk.

When I buy off Ebay or QTH or QRZ I email the owner and ask for telephone number and call and talk to seller. You can tell a lot about the radio and the person by how they answer your questions. I ask them to talk to me ham-to-ham and man-to-man and give me what they really know about the radio. If I do not like what I hear then I walk away. No guarantee you will still not get a problem rig, but most times the person will tell you what they really know about the radio.

Also must be cautious when they say things like it worked last time I tried it or when I put it in storage it worked or I only operate on 80 meters or I dont have an antenna to try it. All words that should cause you to be concerned.

I also ask about what is my "right of return". If they say no return and sale is final, then I usually make a low ball offer if interested at all or I move on and look for another radio.

OK just wanted to make sure you had completed Step 9. If you have correct VCO frequencies at the bottom ,middle and high end of the VFO on each band and most importantly you have close to 1.0rf rms volts on all bands at TP-3 on the RF board then you should have good RX and TX mixer action.

Let us know how you make out using the regular rf signal generator. Sounds like you have the ability to make a sweep generator. There may be a DDS kit available?

Terry K9TW

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Hello Terry

the problem with this is that TS-830M had been tampered with, altered, modified by the previous owner for 11 meters and power to the limit:
-some of the cables in the back were almost charred and I do not know 'how did I conduct
-coils and transformers for the various ranges, apart from the 11 meters, seemed turn at random and the power transformer is not 'original which ones (some power supplies are lower: I 700 V not 800 for example ....!)
-the resistors of both the rectifier is in the final stage had been put in parallel to obtain values similar to the original ones, but with Watt > 2 and value alterated which is absolutely wrong
-the power tubes are the 6146b and the other the 6156w while the other valve is not the original one (the initial part of the code almost unreadable, and is not the correct one)
-capacitors and discharge resistors on the two electrolytic 100 uF, 500V are dropped ,eliminated, and you know how dangerous such a choice!
..... etc. etc.

Unfortunately I had the bad idea to buy online trusting of what is said by the seller and I was wrong

at this point or gave fire to everything or tried to put it back in the running:
I chose the second way:
- I cleaned all the contacts
- I replaced the cables charred (including some high voltage wires close to the chassis)
- I restored the inductance of 6.8 uH in the final stage and from 0.01 uF capacitor
(I have not found the capacitor 1nF class 1, although I would try what I 10Kv 1 nF)
- I replace all electrolytic capacitor in all board's (> 80 element !!!) with exception for freq board because no simple in double printed board remove components without create damage !

After I started to re-check all power and start alignment from step -1 , service manual , and since I had lent a sweep generator , when i am at step 10 , I started doing the calibration:
given that the filter was not absolutely as was apparent from the graph I tried to change T13 T14 T15 but as I said I had to return the instrument because the owner had sold and so are in a situation halfway;
I tried to go back and now I can see the display of the VFO from the bottom to the top, for each band, but BPFA is definitely out of the correct values:
What do I have to lose in an attempt to make and do as you said previous commentary?
the two filters that follow?
no , no ..... do not touch them if I do not have a sweep, but the price is prohibitive besides the fact that I have not even a spectrum analyzer;
i dont know if BP-B BPF-C are altered , i can check but i can't touch without the sweep !

the only tools at my disposal are a frequency meter , borrow an oscilloscope, an usual digital multimeter and a grid-dip homemade

Well I hope I have answered your question.

What would you do in my place ?

this week I should start doing some measurements so you'll know how to proceed;

Ugo

(in the meantime I'm thinking if an Arduino with a varicap and a pair of D/A A/D + the gnuplot program + user program and doing what you said :
I could automate the sampling in steps of 50 or 100 khz tensions
(i can parallelize the rf capacitor with varicap varing voltage ....)
and transmit via socket [fq , voltage] in emitter from arduino to pc ; after with gnuplot reads the vector created and graph the values in a cartesian plane with a jpeg image can be view with refresh automatic (via html / user application ...) ;

This procedure in 5/10 seconds at max can give a correct picture of where are several voltage spikes ..... bah we'll see!)

Ã□Â□Ã□Â□Â I never advise anyone to attempt to adjust any KW hybrid BPFs if they do not have a Sweep Gen. Can always do the old manual method with RF sig gen and plot the as found response curve on graph paper, but almost impossible to properly stagger tune the 3 resonant circuits with this method.Ã□Â□Ã□Â□Â TS-520 has couple of BPF and for life of me cannot figure out way people mess with the slugs on these. Ã□Â□Ã□Â□Â If Ã□Â□Ã□Â□Â you just want to see where they are set then a RF sig gen and RF probe/VTVM and injecting steps

and recording the RF output voltage and then plotting the points is a fun exercise to show the response curve, but it will be a frustrating exercise if you then need to adjust and run another stepped "sweep".Ã□Â□Ã□Â□Â Maybe you can find someone close to you that will have a RF sweep gen that you can borrow? You can do the old fashioned method using a regular RF sig gen and a RV millivolt meter or O-scope and inject 50khz to 100 khz steps at VFO signal input on PLL board and then measure the RF voltage levels at the Emitter of buffer amp Q35. You make yourself a table of frequency vs rf output voltage and then plot the points on a graph paper. Before I got a good Sweep gen I use to plot the points using Excel. When you get close to Fc (5.750mhz) best to use smaller frequency steps and take more points. This method has been used for many years by hams to sweep all kinds of filters and you will get a nice graph of the frequency response curve as you have left the filter adjustments.

For BPF-A Step 10 you are lifting the VFO signal to the PLL and substituting your RF sig gen from about 5.000mhz to 6.500mhz. I would use a frequency counter to make sure you know what the actual frequency of your rf sig generator is. Set sig gen level to 0dBm or 224mv.

Does the S-meter work normally in RX mode with off air signals and/or Marker signal?

The S-meter is a volt meter that monitors the AGC bus in RX mode and the ALC bus in TX mode. This bus is set to approx 3.3vdc and fed from the RF-1 voltage on the AVR board. Any time S-meter goes up scale it is telling you the AGC bus is going lower in voltage from its 3.3vdc reference level. Any time it goes down scale it is telling you the bus voltage is going higher than 3.3vdc. This is very rare. RF-1 is derived from the 9vdc regulated on the AVR board. Never seen them go higher in voltage under key down. If you have DMM or VTVM I would monitor RF-1 at AVR board or at RF board and see what it does when you flip to send. If it goes up then measure 9vdc when you key rig.

Can test Driver stage and ALC indication by turning off the SG switch on rear of rig. Then with heater on , meter in ALC position, Car pot at approx 1200, then key rig and peak the Drive control. If meter pegs full scale right just turn down the Car level pot to get indication off the peg. Try this on all bands. If no ALC indication in Tune try same test in CW mode on all bands. There should be no difference in ALC indication in Tune or CW mode for a given setting of the Car Level Pot.

As I said for ALC indication to peg hard down scale when you key the rig the ALC bus would have to be going higher in voltage from its 3.3vdc level set by RF-1.

I have never seen this. Maybe someone else has experienced it and can share the cause and fix.

After using the standard DeoxIT D5 spray on a TS-530S band switch and spending more time cleaning up the overspray than I spent cleaning the contacts, I switched to a more precise and electrically efficient method of application by employing the contents of a CAIG DeOxIT Liquid 25mL bottle with Needle Applicator.

The DeoxIT in the bottles is even more expensive than the sprays, but since it's 100% product, just a drop on each contact works wonderfully. I used it on my TS-830S's band switch, thus reviving the radio from working marginally on one band to operating perfectly on all.

Hi terry
sorry for delay but when i post a message has a delay cause is too short time in this news group and from post and real view in site , has a delay

thanks for understanding my situation: I am a ham radio and I thought that existed between ham radio operators a minimum of fairness ....
now it is gone and it is no use crying over spilled milk ....!

Regarding the step 9:

"OK ... just wanted to make sure you had completed Step 9. If you have correct VCO frequencies at the bottom, middle and high end of the VFO on each band and most importantly you have to close 1.0rf volts rms on all bands at TP-3 on the RF board then You Should Have good RX and TX mixer action ..... "

the freq are ok, tensions were only slightly different, but are fine now!
the problem is the voltage 1.0 Volt: in some band ok but I have some values more than 3 volts and 28 MHz I've 400/500 mV: since the manual was written 1.0. V + [+2 dB, -1 dB] believed to be in the correct range.

Regarding

"Let us know how you make out using the regular rf signal generator. Sounds like you have the ability to make a sweep generator. There may be a DDS kit available?
"
the idea is a mechanization suggested at the beginning of your process:
I have a RF generator of Mial, 1950/60 with 1 valves, as the mod 145 but has the chance to calibrate even the MF to 455 (the owner is my father's ham 80 years ....:-), but with a stability of frequency incredible;
The valve 6sc7 was almost exausted but in the end I found one and I arrive tomorrow so between Sat & Sun I should be able to try everything

his is an attempt I wanted to do:

vary with arduino via D / A voltage on a varicap in parallel to the variable capacitor of Mial, store the numbers corresponding to the values min and max steps of 1/20; (1/20 is an example : can be use 1/50 or 1/100)
(the main capacitor of rf generator must be placed with varicap ready at start of 5000 Khz - f(varicap, 1/20)
at this point entering a program loop that:
-sets the voltage of the i-th D / A in varicap thus varies the fq of Gen. RF (Fq-initial + Dv) (depending on value produced by D/A of Arduino)
-read for a certain number of times the value read by an other A / D, always connected to arduino in such a way as to have the voltage value by E of Q35 for this i-th step
then store the pair and open a socket to a server application in pc , in my case written in python, which reads the values sent and stores them in a vector;

once the loop the program on arduino freezes for a few moments while the server program reads the values of vector and calls gnuplot to draw the graph with the correspondence:
x fq to step 1/20

y values in mV in E Q35

Okay, maybe it 'a stupid idea but maybe it could work
dds i do not know them very well and I have no problems with microcontrollers such as Arduino or various picxxxxx and languages like python .ecc.....

What do you think?

Ah ... I forgot: J1 must be removed from pll board and the bridge with D27 <---> R44 I have to do, however, also using an external rf right?

Ugo

Subject: [TS-520_820_530_830] Vacuum tube theory videos

I made a couple of short videos showing what happens to the Grid, Cathode, and Screen voltage of a simple amplifier circuit (IF amp in this case) when grid voltage changes by the application of AGC voltage based on the strength of a receive signal. The videos are of the first IF stage, V3, in my Heathkit SB-100. Although the SB-100 is NOT an Kenwood hybrid, the idea behind the videos is to show basic vacuum tube concepts. The same thing applies to your hybrids final amplifier or driver tubes. As the grid voltage varies so does the gain of the tube(s) as shown in the videos. You can perform these simple test yourself but you will need a VTVM or two, the 1Meg probes for each VTVM, and take the time to experiment. If you are studying vacuum tube theory, experiments such as this can easily make what you read/studied, "make sense"!

There are 2 videos, one shows the variations in cathode voltage along with grid voltage (AGC voltage) and the other shows the variations in grid and screen voltage.
\
Both videos begin with the tube operating at maximum gain. As the signal is applied, AGC voltage is produced that is applied to the grid of the tube resulting in a "reduction" in the tube's gain. When the gain is reduced the grid voltage increases (combination of fixed operating bias and AGC voltage), the Cathode voltage decreases due to reduced electron flow in the tube, and the Screen voltage increases due to a reduced voltage drop in the screen circuit. The opposite occurs when the gain is "increased" caused by the reduction in the strength of the receive signal.

If you all remember the many times we have said the importance of measuring voltages, this is a clear example of what we are talking about!

If you are interested in seeing the videos drop me a private email and I'll send them to you. Each video is "10meg" so your Internet service provider/email server must allow you to receive files larger than 10meg.

I hope to have them uploaded to the Files section soon.

The videos can be viewed using Windows Media Player, included with all versions of Windows.

I'm working on another video to show what happens when the a tube that shares the AGC buss with another tube, turns Positive due to excessive gas. It's easy to "simulate" a gassy tube by using a 1.5VDC AA battery and applying that voltage to the grid of one tube we'll call tube "A" while monitor the grid, cathode, and screen voltage of the other tube we'll call tube "B". What do you think will happen to tube "B's" grid voltage? Also what happens to the output signal of both tube "A" and tube "B"?

Ugo:

1.0 rf volts +3dB and -2db tolerance means a high of 1.412 rms volts(4v P-P using O-scope) and a low of 0.794 rms volts (2.24v P-P).

Should never see 3 rms volts VCO signal level at TP-3. 400mv to 500mv is too low for good RX and TX mixer action. 3.0 volts P-P is OK.

I have two TS-830s and my VCO voltage usually ranges from a low of approx 890mv rms @160 meters to a high of approx 1.42 rms volts @ 10 meters.

I cannot spell Arduino or Picaxe let alone program using a Python or an Anaconda!

I am still trying to figure out how to connect the agitator gear box from old washing machine to my RF sig gen frequency air variable capacitor shaft.... I think they call it a Wobbulator?

I think you are asking about moving on to Step 11. Yes you must unplug Conn 1 so that the bandswitch does not bias on any of the matrix diodes. You need to be able to bias on the BPF you want to sweep and not let the bandswitch configure the filters.

You do that by unplugging Conn 1 and using D27 jumper to apply +9vdc to BPF-B switching diodes D42 and D48.

You also jumper from D50 to reverse bias switching diodes D50 and D51 to make sure no test signal back feeds BPF-A or leaks around Mixer Q36.

You then inject 14.100 mhz rf @ 0dBm or 224mv at R111 at Gate 1 of Mixer Q36. Step calls for a 15pf cap but it is not critical and I have used a 50pf cap.

You measure the RF output voltage and frequency at emitter of Q35 same as you did for Step 10. With 14.100mhz @ 224mv applied from your RF sig gen you should read something like 60mv and 24.100mhz . You record 60mv on your data sheet for 14.100mhz and now start stepping up in no more than 100khz steps and record the MV output. As you get nearer to 14.600mhz start using smaller steps around 50khz and take more rf voltage data points so you can clearly see the peak that should occur approx at 14.580mhz which will be 24.580mhz FC of the filter. Should see something close to 175mv signal level at emitter of Q35. I would continue stepping up in frequency and recording MV output until you get to approx 15.600mhz.

Mick,

Each person will have a different answer, I'm afraid. I prefer the 100% solution, as I feel that DeOxit D5 has too much "carrier" or solvent and attracts too much dust. I ONLY use a small drop (or a bit on a toothpick) to clean contacts, and others splash it on too, so each has his own methods of use. I buy the applicator with a "needle" type applicator so I can get a small amount. This stuff is expensive, but the small bottle of 100% will last a long time.
Just an opinion,

It's a known fact that too much of a good thing is not always best. Anytime I work with deoxit and I have a can of spray as well as the needle applicator, you don't need a lot of it. Spray some in a spall spray can cap and use a small brush or even a lint free cloth to dab a bit and apply. I found it at Radio shack. You should never have to spray that much where you spend hours cleaning overspray. Heck, get contact cleaner to clean up the over spray and the contacts and apply minute amounts to the contacts. If you use the spray can, don't press hard on the value button, press "gently". I use DeoXit D5 and F5 spray cancleaner/lubricant and press "gently" on the value button, limiting the amount of cleaner/lubricant being applied to the area being cleaned.

Also do you follow your cleaning process using generous amounts of compressed air or canned air to remove the cleaner residue on the component, surrounding components, wiring, and PC boards being cleaned? If not then you should be doing that.

I've been using DeoXit D5 and F5 cleaner/lubricant for years and never experienced any damage to components, wiring, and PC boards that many people who use these cleaners/lubricant seem to speak of. Every time I clean a switch, pot, tube socket (vacuum tube gear) or connection/connector on a PC board, I immediately follow the cleaning process by using generous amounts of canned air (don't have a air compressor) to remove any/all cleaner residue. Using this procedure I have never sustained any damage to any component, switch, tube socket, connector, PC board or pot using DeoXit D5 and/or F5 contact cleaner/lubricant.

Hi Terry

regards :

"
....
1.0 rf volts +3dB and -2db tolerance means a high of 1.412 rms volts(4v P-P using O-scope) and a low of 0.794 rms volts (2.24v P-P).
Should never see 3 rms volts VCO signal level at TP-3. 400mv to 500mv is too low for good RX and TX mixer action. 3.0 volts P-P is OK.
I have two TS-830s and my VCO voltage usually ranges from a low of approx 890mv rms @160 meters to a high of approx 1.42 rms volts @ 10 meters.
....
"

this is a problem for me because my levels are not in range
[2.24 Vpp , 4.0 Vpp]
i repeat step 9 and recheck !

".............
I cannot spell Arduino or Picaxe let alone program using a Python or an Anaconda!

:-))

"
I am still trying to figure out how to connect the agitator gear box from old washing machine to my RF sig gen frequency air variable capacitor shaft.... I think they call it a Wobbulator?
............."

Do not think that Python is difficult: if I can make the settings of the bpf-a at least to an acceptable level want to try to realize what I have said
The wobbulator remember me a piano Yamaha with a servo-command for play the music without pianist ...no no .... my initial idea is join then varicap in parallel to air capacitor of old rf generator , with dc block , for light modification of capacity in range required by step 10 11 12

".............
I think you are asking about moving on to Step 11.
....
"

No , i am locked at step 10 until this weekend and the question relate
unplugging J1 is relate step-10 with bridge with wire from d27 to r44 ;

"
....

Yes you must unplug Conn 1 so that the bandswitch does not bias on any of the matrix diodes. You need to be able to bias on the BPF you want to sweep and not let the bandswitch configure the filters.
You do that by unplugging Conn 1 and using D27 jumper to apply +9vdc to BPF-B switching diodes D42 and D48.
You also jumper from D50 to reverse bias switching diodes D50 and D51 to make sure no test signal back feeds BPF-A or leaks around Mixer Q36.
You then inject 14.100 mhz rf @ 0dBm or 224mv at R111 at Gate 1 of Mixer Q36. Step calls for a 15pf cap but it is not critical and I have used a 50pf cap.
You measure the RF output voltage and frequency at emitter of Q35 same as you did for Step 10. With 14.100mhz @ 224mv applied from your RF sig gen you should read something like 60mv and 24.100mhz . You record 60mv on your data sheet for 14.100mhz and now start stepping up in no more than 100khz steps and record the MV output. As you get nearer to 14.600mhz start using smaller steps around 50khz and take more rf voltage data points so you can clearly see the peak that should occur approx at 14.580mhz which will be 24.580mhz FC of the filter. Should see something close to 175mv signal level at emitter of Q35. I would continue stepping up in frequency and recording MV output until you get to approx 15.600mhz.

44398. TS-520 Birdies

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-05 16:42:22 UTC
From: <wagstw46@...>
Topic: 41008 Message: 44398

Off list question about TS-520 "birdies".

TS-520 or TS-520S it is common to have two "birdies" that are more prominent than others. One at approx 3.740mhz and one at 21.200mhz.

Can recognize a "birdie" as it is internally generated and will most likely not be able to peak it with the Drive control because it is originating at the 1st Mixer on RF board downstream of the Ant Coil board. It will also typically have a faster tuning rate as you vary the VFO.

The birdie at 21.200 will most likely have no indication on the S-meter and will not be heard with antenna connected and normal background levels. The 3.740mhz one is the real problem and Kenwood made two "fixes" to help suppress this birdie.

The source of the 3.740mhz birdie is the 1st RX Mixer on RF board where you mix 12.395mhz with the incoming rf off air signal. Output from the Mixer is the Receiver Intermediate Frequency or RIF signal. In this case 12.395mhz Het Osc is the LO and 3.740mhz is the rf input signal to the mixer. Mixer output is sum and difference and other less significant. 12.395-3.740 = 8.655mhz RIF. There is a parallel resonant tank circuit at output of the RX mixer tuned to the new RIF frequency range that should block the offending signal but is not entirely effective in doing so. I think where the problem comes in is the Het Osc LO signal level is high and is present at a significant level in the output of the dual gate mosfet mixer along with the needed new 8.655 RIF. There is a diode switch D2 between the Drain of the Mixer and the Tank circuit and my guess is this is where the mixing of the Het Osc and RIF signal is occurring, but I am not sure.

This results in a pretty strong birdie at 3.740mhz. (12.395 - 8.655 = 3.740 mhz). This can result in a S3 to S4 indication and loud tone in speaker. Usually if you switch antenna switch off ground or dummy load positions the birdie cannot be heard or will be at a low audible level and wont compromise your ability to copy signals at or near 3.740Mhz.

In the TS-520 Kenwood engineers placed a series resonant trap at output of 1st RX Mixer. It is L2 and C15 on the RF board at the Drain of mixer Q4. You adjust L2 for a minimum indication on the S meter at 3.740. You will not be able to reduce the level to S0. Usually you can get it down to around S1 to S2. Typically it requires adjusting the slug to the top of the former (least inductance).

On the TS-520S Kenwood moved this L2 tuned trap from the Rx mixer on the RF board to the IF board at the output of the BPF. It is renamed coil T13 and cap C62. The trap is a little more effective at this new location, but still typically cannot complete null out the 3.740 mhz signal. May get S-meter down to S1 or so,but can still hear the tone in the speaker as you tune across it. Again with antenna on and strong signals on 80 meters most owners do not concern themselves with this birdie. Some even report never hearing it as they never have antenna removed or grounded on the rig or do not operate around 3.740mhz. .

If you want to completely null it on your TS-520 (zero on S-meter and no hint of tone in speaker) you can make a 12.395 mhz series resonant trap (miniature adjustable inductors and

caps are available from Surplus of Nebraska) or do like I did and harvest a L2/C15 from a bad TS-520 RF board.

Tack solder the cap and coil in series and then tack them from TP-2 terminal post on the IF board to chassis ground. Preset the core to near top of former or maybe 1 turn out of the top. Tune to 3.740Mhz and alternately tune the original L2 on the RF board and the new L2 on the IF board and you should be able to completely null it.

Addition of the new trap at the IF board will not effect receiver operation.

I have confirmed there is no effect on RX by checking the AGC threshold on 80 meters around at low end of the band before and after the addition of a 2nd series resonant 12.395 mhz trap.

You should be able to add the same trap to the TS-520S back at the RF board if needed , but I have not tried that.

44399. TS-530S vs. TS-830S CW filter behavior

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-05 18:23:30 UTC
From: Craig Roberts
Topic: 41008 Message: 44399

Hiya gurus,

I posed this question the other day, but have decided to rephrase it with some additional -- possibly useful -- information:

I have equipped both my TS-830S and TS-530S with Kenwood/Trio 500 Hz CW filters.

The TS-830S is loaded with filters for both IFs. It behaves superbly.

The TS-530S is loaded with the 500 Hz CW filter and the 1.8 KHz narrow SSB filter jumpered so that the "normal" CW position is now 1.8 KHz and the "narrow" pushbutton yields 500 Hz CW. I can also, of course, select between "normal" 2.4 KHz SSB and "narrow" 1.8 KHz SSB. Very slick -- just like my really cool ITT Mackay Marine 3031-A shipboard operator wannabe receiver.

Problem (maybe) is with the 530S:

In the narrow 500 Hz CW position, signals are dramatically attenuated and the passband sounds much more restricted than 500 Hz. It sounds more like 250 Hz or less. I mean, it's nice having essentially no background noise on the signals, but weak signals are nearly if not completely lost. By contrast, the 500 Hz CW position on the dual-IF 830S sounds wider and is not attenuated nearly as much.

Is this phenomenon somehow related to single vs. dual conversion (huh?) or do I have a bum CW filter in the 530S? I have checked and re-checked installation and jumpering.

Thanks and 73,

Craig
W3CRR

44400. 530/830 digital mode how-to

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

For once, I'll pass along some info that might be useful to someone else.

Every so often a question about running digital modes and/or restricting our radios' power output will be posed. This addresses both.

I am running digital modes on my 830S (and 530S) via my desktop computer and a SignaLink USB interface with pleasing results (after sufficient, frequency stabilizing warmup).

The SignaLink's output is connected directly to the radio's mic jack. The received signals are routed from the very useful "line output" jack on my Kenwood SP-230 speaker.into the SignaLink's back panel "speaker" jack. This avoids muting the receiver as would occur if the radio's speaker or headphone jack was employed. Audio can be tapped from the radio's accessory DIN jack to avoid reeiver audio muting, as well.

I tune the 830's transmitter to full output as usual, then limit the radios' power output to about 40 watts by regulating the "transmit" pot on the SignaLink interface. The setup works very neatly and obviates the "do I Iimit output power with mic gain or drive or load control?" question.

Other interfaces would work just as well, naturally.

I run PSK-31 most often with RTTY, Hellschreiber and SSTV following. "FLdigi" freeware accomodates them all and more. FLdigi also incorporates a CW decoder which comes in handy at 2 a.m. when I'm too fagged out to copy anything past 20 wpm without nodding off.

73,

Craig

Ugo:

Just to be 100% certain.

Are you confusing the DC voltages at TP-1 that you measure with a DMM with the VCO RF output voltage levels at RF board TP-3? I doubt it but needed to ask.

You measure and adjust the 6 DC voltages first per the table. Then you measure the VCO RF voltage output level. Then you swing the VFO from end to end travel on each band and make sure the Digital display does not blank out.

If you are measuring the VCO RF output level with an O-scope what is the bandwidth of that scope? You need to be able to measure up to approx 38mhz reasonably accurate.

A 100mhz scope will read approx 3% low at 30mhz. A 20Mhz BW scope (typical of many home hobbyist) would read approx 3% low at 7mhz and would read approx 29% low at 20mhz (-3dB or 70.7%). A 20mhz scope is not very good for Kenwood RF voltage measurements unless you understand and take into account the bandwidth voltage derating.

Scope makers will tell you as general rule of thumb to use a scope that has 3 to 5 times the bandwidth of the max freq you intend to measure. For our Kenwood work max frequency is around 35 to 40 mhz so a 100mhz scope works pretty well.

If people dont understand the effect of scope BW they can get confused and think there is a problem with the radio or the measuring configuration and chase their tale trying to resolve it.

If you dont have decent scope might be better off with RF probe/VTVM to measure rf voltage levels.

unplugging J1 is relate step-10 with bridge with wire from d27 to r44 ;

"
.....
Yes you must unplug Conn 1 so that the bandswitch does not bias on any of the matrix diodes. You need to be able to bias on the BPF you want to sweep and not let the bandswitch configure the filters.
You do that by unplugging Conn 1 and using D27 jumper to apply +9vdc to BPF-B switching diodes D42 and D48.
You also jumper from D50 to reverse bias switching diodes D50 and D51 to make sure no test signal back feeds BPF-A or leaks around Mixer Q36.
You then inject 14.100 mhz rf @ 0dBm or 224mv at R111 at Gate 1 of Mixer Q36. Step calls for a 15pf cap but it is not critical and I have used a 50pf cap.
You measure the RF output voltage and frequency at emitter of Q35 same as you did for Step 10. With 14.100mhz @ 224mv applied from your RF sig gen you should read something like 60mv and 24.100mhz . The SignalLink "Transmit" pot does the same thing that "lowering" the MIC gain does except it does it on the SignalLink interface. MFJ and other sound card interfaces do the same thing except most of them have the adjustable "Transmit" pot internal, not on the front panel of the sound card interface.

PSK and other sound card modes use "audio" signals for both transmit and receive. The computer software converts the keys pressed into "mark" and "space" audio tones that are fed from the sound cardoutput through the sound card interface and quite often to the MIC socket connection. The "reverse" occurs in receive, the PSK tones are fed from the receiveaudio output to the sound card interface, from the sound card interface to the sound card's input, where the "mark" and "space" tones are converted into "ASCII" letters, numbers, and "cute" faces (when the software sees the "lol" sequence is found as part of the decoded data).

The sound card interface typically has 2 methods of keying the transmitter

1. VOX
2. PTT

Vox doesn't require any wiring to the microphone socket's PTT terminal and ground. All that's required is the transceiver's VOX is turned ON and adjusted properly.

PTT, on the other hand, requires a serial cable, typically a "straight through" serial cable, that has RTS and DTR pins avalable. The PSK or other digital software activates the desiredserial control signal and the interface is configured to use the desired/selected control signal for PTT. Only one is used/selected for PTT, not both as many hams tend to believe. The same thing applies to USB to RS-232 adapters.

Sound card interfaces are very easy and inexpensive to build. I made an RS-232 to TTL/CMOS andTTL/CMOS to RS-232 CAT interfaceas part of the complete Sound Card interface.

The serial interface segment used a simple MAX232 16 pin DIP chip. The MAX232 chip cost about 89 cents at Mouser.

All you need to build the CAD interface, using the MAX232chip, is the MAX232 data sheet (see the link below).

http://www.mouser.com/ds/2/256/MAX220-MAX249-67423.pdf

The data sheet shows you how to build a simpleTTL/CMOS to RS-232/RS-232 to TTL/CMOS circuit. The MAX232 comes in a 16 pin "Dip" chip or SMD chip. You also can design and have made, a PC board using ExpressPCB CAD

software. I use this software a lot to make PC boards for my projects. My most recent project where I used ExpressPCB CAD software was to have a dual power supply PC board made for my Heathkit HG-10B and VF-1 VFOs.

Power for the MAX232 chip was obtaed from the 13.6VDC DIN socket and ground on the rear of the FT-857D. I added a 7805 "5 volt" regulator and bypassed the regulator's inputand output with .01ufd caps. I was able to control the FT-857D at the transceiver's highest serial speed which I think was 38.4K.

The sound card portion of the interface used inexpensive 1:1 Radio Shack audio transformers. Inter-connecting cables were cheap stereo/DVD/VCR shielded cables with RCA plug on one end and 3.5mm plug on the other.

I don't operate digital modes anymore so I disassembled the interface, used the cabinet for adifferent project. But, as you can see, you can build your own sound card interface for most any transceiver plus learn something in the process.

Hi, I have the R820 rx, the signal drops off alarmingly. I got an icom 7410 selectivity goes down to 50 Hz with dsp filtering, plus a good notch filter. Wish I had gone over to this new stuff years ago. 73 de ian g3yrq

Not exactly the same rig but my TS520 got the kenwood 400 Hz filter installed by me as soon as I could get the optional filter shipped. and the TS440s came from previous owner with the 500 Hz optional filter in it. Both reduced signals by only about 1 S unit.

Subject: [TS-520_820_530_830] TS-530S vs. TS-830S CW filter behavior

Hiya gurus,

I posed this question the other day, but have decided to rephrase it with some additional -- possibly useful -- information:

I have equipped both my TS-830S and TS-530S with Kenwood/Trio 500 Hz CW filters.

The TS-830S is loaded with filters for both IFs. It behaves superbly.

The TS-530S is loaded with the 500 Hz CW filter and the 1.8 KHz narrow SSB filter jumpered so that the "normal" CW position is now 1.8 KHz and the "narrow" pushbutton yields 500 Hz CW. I can also, of course, select between "normal" 2.4 KHz SSB and "narrow" 1.8 KHz SSB. Very slick -- just like my really cool ITT Mackay Marine 3031-A shipboard operator wannabe receiver.

Problem (maybe) is with the 530S:

In the narrow 500 Hz CW position, signals are dramatically attenuated and the passband sounds much more restricted than 500 Hz. It sounds more like 250 Hz or less. I mean, it's nice having essentially no background noise on the signals, but weak signals are nearly if not completely lost. By contrast, the 500 Hz CW position on the dual-IF 830S sounds wider and is not attenuated nearly as much.

Is this phenomenon somehow related to single vs. dual conversion (huh?) or do I have a bum CW filter in the 530S? I have checked and re-checked installation and jumpering.

Thanks and 73,

Craig

Subject: [TS-520_820_530_830] TS-520 Birdies

Off list question about TS-520 "birdies".

TS-520 or TS-520S it is common to have two "birdies" that are more prominent than others. One at approx 3.740mhz and one at 21.200mhz.

Can recognize a "birdie" as it is internally generated and will most likely not be able to peak it with the Drive control because it is originating at the 1st Mixer on RF board downstream of the Ant Coil board. It will also typically have a faster tuning rate as you vary the VFO.

The birdie at 21.200 will most likely have no indication on the S-meter and will not be heard with antenna connected and normal background levels. The 3.740mhz one is the real problem and Kenwood made two "fixes" to help suppress this birdie.

The source of the 3.740mhz birdie is the 1st RX Mixer on RF board where you mix 12.395mhz with the incoming rf off air signal. Output from the Mixer is the Receiver Intermediate Frequency or RIF signal. In this case 12.395mhz Het Osc is the LO and 3.740mhz is the rf input signal to the mixer. Mixer output is sum and difference and other less significant. 12.395-3.740 = 8.655mhz RIF. There is a parallel resonant tank circuit at output of the RX mixer tuned to the new RIF frequency range that should block the offending signal but is not entirely effective in doing so. I think where the problem comes in is the Het Osc LO signal level is high and is present at a significant level in the output of the dual gate mosfet mixer along with the needed new 8.655 RIF. There is a diode switch D2 between the Drain of the Mixer and the Tank circuit and my guess is this is where the mixing of the Het Osc and RIF signal is occurring, but I am not sure.

This results in a pretty strong birdie at 3.740mhz. (12.395 - 8.655 = 3.740 mhz). This can result in a S3 to S4 indication and loud tone in speaker. Usually if you switch antenna switch off ground or dummy load positions the birdie cannot be heard or will be at a low audible level and wont compromise your ability to copy signals at or near 3.740Mhz.

In the TS-520 Kenwood engineers placed a series resonant trap at output of 1st RX Mixer. It is L2 and C15 on the RF board at the Drain of mixer Q4. You adjust L2 for a minimum indication on the S meter at 3.740. You will not be able to reduce the level to S0. Usually you can get it down to around S1 to S2. Typically it requires adjusting the slug to the top of the former (least inductance).

On the TS-520S Kenwood moved this L2 tuned trap from the Rx mixer on the RF board to the IF board at the output of the BPF. It is renamed coil T13 and cap C62. The trap is a little more effective at this new location, but still typically cannot complete null out the 3.740 mhz signal. May get S-meter down to S1 or so,but can still hear the tone in the speaker as you tune across it. Again with antenna on and strong signals on 80 meters most owners do not concern themselves with this birdie. Some even report never hearing it as they never have antenna removed or grounded on the rig or do not operate around 3.740mhz. .

If you want to completely null it on your TS-520 (zero on S-meter and no hint of tone in speaker) you can make a 12.395 mhz series resonant trap (miniature adjustable inductors and caps are available from Surplus of Nebraska) or do like I did and harvest a L2/C15 from a bad TS-520 RF board.

Tack solder the cap and coil in series and then tack them from TP-2 terminal post on the IF board to chassis ground. Preset the core to near top of former or maybe 1 turn out of the top. Tune to 3.740Mhz and alternately tune the original L2 on the RF board and the new L2 on the IF board and you should be able to completely null it.

Addition of the new trap at the IF board will not effect receiver operation.

I have confirmed there is no effect on RX by checking the AGC threshold on 80 meters around at low end of the band before and after the addition of a 2nd series resonant 12.395 mhz trap.

You should be able to add the same trap to the TS-520S back at the RF board if needed , but I have not tried that.

Hello to all & I hope this finds you well.

One alternative is to buy the D-5 Aerosol and if you have a gal in your life who uses nail polish and likely has an old, empty, or nearly so, or no longer valid color nail polish bottle you can dump the stuff inside and use acetone or finger-nail polish remover to clean the bottle & brush. Then by applying light pressure on the valve button you can fill the bottle w/ a small amount of D5 and use the brush or a needle applicator to introduce the product into the easy to reach places. In fact; when de-oxit was first marketed this is how it came. The original product was Super Cramolin amd came in two types, a red and a blue. The stuff was supplied in nail polish bottles and included in the kit were various applicators in a plastic case. Worked really well in broadcast equipment and made us happy campers. The advantage to this approach is you still have the aerosol and guide tube in the event you find a particularly hard to reach spot, and you
only are buying one product. I hope this helps.

Keep your paddles wet & your socks dry,

Mike K8SYN

A DSP filter is a totally different animal than a narrow crystal lattice filter. For example,, a 500Hz 8-pole crystal lattice filter used for CW will have significantly more Insertion Loss than a 2.4kHz 8-pole crystal lattice filter used for SSB. The Insertion Loss differential can be seen on the S-meter, even with a calibrator signal.

The individual TS520 owner will decide if it is a problem or not.

I dont want to tune any of my Kenwood Hybrid radio VFOs thru the 0 to 500 tuning range and find a standing S8 or S9 carrier at any point on any band.

That is exactly what you will find at 3740 on a TS520 if someone has fooled around with the wave trap coil L2. Each owner will decide if that is a problem for them or not.

An inquisitive owner (like the one who asked me about this) would be interested in knowing what causes this birdie and if there is anything he can do to reduce its level or eliminate it. My response was directed to those owners.

I could have summarily dismissed him by telling him it is "not a problem" and not to concern himself about it. That is the response of an old school psuedo guru who has no idea why it is there and will decide what a new person needs to know. I grew up in a system where the master employed the "KIP" principle (knowledge is power) and they decided what you needed to know. Often sending you for a tool they didnt really need while they made the secret adjustment. As I grew older and wiser I discovered most of them were not so smart and very protective of of their positions. Often they had good hand skills, but really had no fundamental understanding of how and why it worked.

I decided long ago I wanted everyone who worked for me to be smarter and better and to advance beyond my station and I would be proud to have had some small part in their education by freely sharing what I had learned.

As I explained for the inquisitive TS520 owners interested in learning how their radios work the 3740 birdie can be reduced from S8/S9 level to approx S3/S4 level by proper adjustment of L2 on RF board and can be eliminated by adding a 12.395mhz trap at the IF board as the TS520S employs.

I also stated that with the antenna connected the S3/S4 birdie is usually masked by the background and there should be no problem with signal copy on and around 3740.

"Usually if you switch antenna switch off ground or dummy load positions the birdie cannot be heard or will be at a low audible level and wont compromise your ability to copy signals at or near 3.740Mhz. "

Subject: [TS-520_820_530_830] TS-520 Birdies

Off list question about TS-520 "birdies".

TS-520 or TS-520S it is common to have two "birdies" that are more prominent than others. One at approx 3.740mhz and one at 21.200mhz.

Can recognize a "birdie" as it is internally generated and will most likely not be able to peak it with the Drive control because it is originating at the 1st Mixer on RF board downstream of the Ant Coil board. It will also typically have a faster tuning rate as you vary the VFO.

The birdie at 21.200 will most likely have no indication on the S-meter and will not be heard with antenna connected and normal background levels. The 3.740mhz one is the real problem and Kenwood made two "fixes" to help suppress this birdie.

The source of the 3.740mhz birdie is the 1st RX Mixer on RF board where you mix 12.395mhz with the incoming rf off air signal. Output from the Mixer is the Receiver Intermediate Frequency or RIF signal. In this case 12.395mhz Het Osc is the LO and 3.740mhz is the rf input signal to the mixer. Mixer output is sum and difference and other less significant. 12.395-3.740 = 8.655mhz RIF. There is a parallel resonant tank circuit at output of the RX mixer tuned to the new RIF frequency range that should block the offending signal but is not entirely effective in doing so. I think where the problem comes in is the Het Osc LO signal level is high and is present at a significant level in the output of the dual gate mosfet mixer along with the needed new 8.655 RIF. There is a diode switch D2 between the Drain of the Mixer and the Tank circuit and my guess is this is where the mixing of the Het Osc and RIF signal is occurring, but I am not sure.

This results in a pretty strong birdie at 3.740mhz. (12.395 - 8.655 = 3.740 mhz). This can result in a S3 to S4 indication and loud tone in speaker. Usually if you switch antenna switch off ground or dummy load positions the birdie cannot be heard or will be at a low audible level and wont compromise your ability to copy signals at or near 3.740Mhz.

In the TS-520 Kenwood engineers placed a series resonant trap at output of 1st RX Mixer. It is L2 and C15 on the RF board at the Drain of mixer Q4. You adjust L2 for a minimum indication on the S meter at 3.740. You will not be able to reduce the level to S0. Usually you can get it down to around S1 to S2. Typically it requires adjusting the slug to the top of the former (least inductance).

On the TS-520S Kenwood moved this L2 tuned trap from the Rx mixer on the RF board to the IF board at the output of the BPF. It is renamed coil T13 and cap C62. The trap is a little more effective at this new location, but still typically cannot complete null out the 3.740 mhz signal. May get S-meter down to S1 or so,but can still hear the tone in the speaker as you tune across it. Again with antenna on and strong signals on 80 meters most owners do not concern themselves with this birdie. Some even report never hearing it as they never have antenna removed or grounded on the rig or do not operate around 3.740mhz. .

If you want to completely null it on your TS-520 (zero on S-meter and no hint of tone in speaker) you can make a 12.395 mhz series resonant trap (miniature adjustable inductors and caps are available from Surplus of Nebraska) or do like I did and harvest a L2/C15 from a bad TS-520 RF board.

Tack solder the cap and coil in series and then tack them from TP-2 terminal post on the IF board to chassis ground. Preset the core to near top of former or maybe 1 turn out of the top. Tune to 3.740Mhz and alternately tune the original L2 on the RF board and the new L2

on the IF board and you should be able to completely null it.

Addition of the new trap at the IF board will not effect receiver operation.

I have confirmed there is no effect on RX by checking the AGC threshold on 80 meters around at low end of the band before and after the addition of a 2nd series resonant 12.395 mhz trap.

You should be able to add the same trap to the TS-520S back at the RF board if needed , but I have not tried that.

Hi Terry

The 12 voltage at step 9 appear normal , i hope
but the Voltage at TP3 (RF Board) is dropped as i report :

```
--------VFO-----------
Band ! 0 250 500 ! TP-3 Volt-pp
=====!=========================================
1.5 ! .. 3.99 5.62 ! 2.3
3.5 ! 2.94 3.76 4.67 ! 2.2
7 ! 6.2 4.78 3.08 ! 1.2
10 ! 5.76 5.03 4.13 ! 0.6
14 ! 3.7 4.5 5.73 ! 0.4
18 ! 6.2 5.07 3.77 ! 0.5
21 ! 2.4 3.5 4.58 ! 0.5
24 ! 2.7 3.57 4.24 ! 0.2
28 ! 6.12 5.83 5.53 ! 0.2
! 5.53 5.19 4.82 ! 0.2
29 ! 4.82 4.36 3.84 ! 0.2
! 3.84 3.23 2.55 ! 0.2
```

The values are found with a professional oscilloscope two track 100 Mhz , thus the Oscilloscope is OK

The Value i found for step 6 ok are DC but the rf voltage
at tp3 are found with this oscilloscope and are expressed as Vpp (i check even the trigger level if values are x1 or x10 or other but nothing) ; also for first 8 steps all values are correct.

the only strange thing is that the tp-3 in the RF board is not an anchor point but a component never seen, it looks like a resistance but did not color it seems to be black and I took the part of the top folder: this evening I will try to see if it is actually a jumper from the side trying pll board,d40 to redo the measures even though I think it's the same thing

other strange thing: why the voltages that I have on TP-3 are decreasing from 1.5 to 28 and those that have you going to grow?

there is something wrong and should not be a small thing!

Ciao
Ugo

44413. Not a HYBRID, but need advice. TS-660.

Topic: 41008 Message: 44413

If possible, for to keep from annoying anyone, reply to my email if you wish, rather than to this list?

Kenwood TS-660, might be able to get one for probably under $200, but it's in need of work at the outset.

There seems to be a problem with one or more of the VCO inputs to the first mixer. That's the horseback opinion of the current owner, who says he is going nearly blind, due to age, and can't fix it himself. So he says anyway, and after talking to the gentleman I tend to believe him.

So. Are 660's reasonably repairable? I have found the manual sites, with the usual schematics and tech notes and all that. There's even another Yahoo group, I think, that specializes in these rigs. (I know for sure there's one for the TS-440/SAT.)

Given that I'm not even remotely afraid of getting 'under the hood,' and that I have at least a good start on the required instruments, is there a decent probability that this can be fixed? I know ZERO about these rigs, so if you have an opinion of them I'd love to hear it. Is losing the VCO an Achille's Heel for this model, indicative of MUCH worse coming soon, perhaps?

For information's sake, I'm considering getting this because the TS-520 doesn't cover 6, 12, or 15 meters, mostly. If there is a better model, preferably Kenwood - but not necessarily, that you would recommend for the 15- through 6- meter bands (and up, 70 MHz would be nice to try on, I think) I would like also to hear about it.

License I have. Some bit of knowledge I have and am rapidly gaining more from this list.

Heck, even ANTENNAS I can have and am getting together most rapidly.

But radios, and knowledge of the various good and bad ones out there, I have NOT. Advice and recommendations would be appreciated. (No the local club is useless for this, they're transients mostly, college students at the University from which I am retired. It's almost entirely VHF and UHF around here. And most of the Hams who worked HF which I have known in the past, have, well, passed - S.K. Svyazy Konets. Silent Keys.)

Do note, however, that PRICE IS AN OBJECT. If I can fix something and save a considerable pile of wonga in the doing, that makes up quite a bit for starting with yet another broken-from-the-start radio. Getting a reasonable price on one that's -working- would be even better....

(There are health reasons in here as well, I've got a limited window of mobility left to work in before the witch-doctors lock me up tight to a chair. I'm trying to get set up before that happens.)

Thanks in advance. Off-list would be fine, so it doesn't bother anyone here, please.

Topic: 41008 Message: 44414

Come on, Will... You know the drill, hybrid or not:

If you are not an experienced and well qualified technician:

1) Remove all circuit boards.
2) Using your Hakko 808 desoldering tool and companion FX-951 soldering station, resolder every connection in the radio.
3) Clean each switch contact, potentiometer, cable header and socket carefully and sparingly with DeoxIT. Avoid any drips, overruns or oversprays.
4) Rebuild the band switch employing either the "soldered jumper" or "conductive ink" method (your choice).
5) Reassemble the radio.
6) Tighten every fastener in the transceiver (do not overtighten).

If the radio is still fully or partially inoperative:

1a) Take precise voltage and resistance measurements at the junctions of each pair of components in the transceiver employing your VTVM, DVM, frequency counter, sweep generator and/or scope as appropriate and record the readings.
2a) Post the results on this forum and await responses.

The responses will vary in diagnosis (and opinion) but, among them, will narrow the problem down to no more than 63 suspected components.

1b) Order all parts mentioned from Mouser.
2b) Employing the tools listed in step 1 above, replace said components.
3b) Repeat steps 3 through 6 above.

If radio is still fully or partially inoperative:

1d) Remove cabinet and immerse transceiver chassis in mild solution of ordinary dish soap and distilled water for four hours.
2d) Rinse radio thoroughly with warm, distilled water.
3d) Blow dry chassis thoroughly with two-stage air compressor (65 - 75 psi). Make sure air stream is clean and dry.
4d) Expose chassis to direct sunlight no fewer than 148 hours at a temperature between 24 and 33 degrees Celsius.
5d) Install chassis in cabinet.

If radio is still fully or partially inoperative:

1e) Double box and ship transceiver to Terry, Ken, Jim or Old Ham Dave. Avoid packing with those pesky, static-ridden Styrofoam (TM) "peanuts". They are extremely annoying and could cause the repair tech to charge an additional $100 "handling fee." This would be fully justified.

Your radio will be returned in working order within 21 days after replacement of "R131" and "D23", neither of which will have been mentioned by forum posters.

Good luck & 73,

Craig
W3CRR

Hi Ugo

Yes these test points look like a small resistor. They are found with one end terminated on the board and the free end coiled to allow connecting a mini-grabber test lead. At TP-3 it is placed in series and has very low resistance maybe around 0.10 ohms and half of that is due to the resistance of the DMM test lead and clips.

It is good to measure VCO signal level at TP-3 because it tells you that the coax cable and connectors are good from the PLL board to the RF board. Approx 1.0 rms or 2.828 P-P VCO level is needed at RX and TX Mixers for good RX and TX performance. I have seen bad connections at the coax connectors at each end and one time the cable pulled off the connector.

Good idea to measure levels at D40 on PLL. If you have good readings at D40 then need to pull coax jumper off and re-seat it at each end.

I dont think the coax cable is the problem as you do have voltage at one end of VFO tuning range.

I looked at my notes and I see that the level at 0, 250, and 500 does not very much from Zero to 500. No more than 50 mv and usually less than this in the 10 to 15 mv range.

My lowest voltage levels were on 1.5mhz at approx 870mv rms or 2.46v P-P. On 20 meters approx 945mv or 2.67v P-P. On all other bands approx 1200 mv to 1300 mv or approx 3.5v P-P from zero to 500 VFO tuning range.

Ugo:

Lets talk about 20 meters (14mhz). Here is what I understand you found at Step 9. Let me know if this is correct.

DC voltages measured at TP-1 on PLL Board.

Frequencies measured at D40 on PLL board or at TP-3

VFO 0 = 3.70vdc @ 22.83mhz

VFO 250 = 4.50vdc @ 23.08mhz

VFO 500 = 5.73vdc @ 23.33mhz.

VCO output at TP-3 on RF board = 0.40 p-p at VFO 0-250-500 positions

Also, are you reporting you have approx 1.0 to 2.0 p-p rf volts at TP-3 on 1.5, 3.5 and 7.0 mhz. All other bands have 0 rf volts output at TP-3.

If you had a bad cable or connectors or solder connections you should not have any VCO output at TP-3 on some bands and not on others.

Let me know if what I have stated here is correct.

44417. Anyone have pics of TS-520SE innards? Rectifier board in particular?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-08 05:28:58 UTC
From: Wes Will
Topic: 44331 Message: 44417

First off, I love this group, the people, and the knowledge that gets passed around by them. The forum is a fantastic resource.

But.....

The Yahoo host and the methods they use for storing information are enough to drive a man mad.

Here is why (partly):

I've just been looking for pictures of the inside of a 520SE, around the rectifier board of course. Found a couple that look like they might be just what I need.

Except, seeing as they're on this Yahoo thing, they're not available as photos to enlarge so I can see the detail and colours I need and find out if they are what I need.

(They're some sort of crazy slide show, meant to "help" the gormless I guess, but which instead drives me absolutely bug-snot crazy trying to manipulate it to see the colours of the wires at each wire-wrap point. I guess I have too much gorm...

If it was just a photo file, it would be simple. Seeing as it's not, it is far from simple (and most annoying).

Can't seem to find a way to get them out as photos inside Yahoo's excessively "helpful" facilities, so I guess I'll look for an add-on utility for Firefox, to maybe get something useful out.)

And while I'm looking for a way around, here's a quick question. Does someone with a 520SE have the time (and a camera) to snap a shot of the rectifier board?

The one I have has white-with-coloured-stripe wires.

The replacement board has only solid-coloured wires.

My original photos from before any of this started seem to be missing. I believe my wife "borrowed" the memory device I had them on, and wiped it to make room for files from her school. (She's an elementary school teacher, and rather un-technical to say the least. Fantastic school teacher, but fights with technology more complex than a pencil sharpener.)

The few that are the same (solid colours, six of them red, in two gauges...), I have traced back in the chassis and on the schematic, and those are connected. The transformer wires are all connected, those were easy enough. But the others, they don't match with the replacement

board. I've gotten some of them straight, the two green ones gave me some fun, but I traced them back to the proper points.

I do NOT want to get this wrong. So, can someone send me, or post a URL for a picture of, this particular part of the chassis? WITH the bi-coloured wires, please?

In particular, the wires coloured white with a:

grey stripe;
red stripe;
blue stripe;
yellow stripe;
green stripe;
violet stripe;
grey stripe (yes, there are two of them, on opposite sides of the board).

I really don't want to trace them all back if I don't have to. I will, of course, but I'd rather cheat with a photo, if I could. Those seven connections are what stand between me and a probably-working radio. And I DO NOT want to screw this up. (That un-technical wife is still upset about my buying a radio that turned out to be busted....)

So, anybody got a link to a photo?

Ugo:

Two more clarifying questions:

1. Is Conn 1 plugged in while taking the Step 9 voltages?

2. Is the Digital Display blanked (off) for the bands where you have no VCO output voltage at TP-3?

Topic: 44372 Message: 44424

I'd be mostly guessing, but from the voltage being way low on the grid, is it the grid resistor being open, or far out of tolerance (ten or more times the nominal value)??

Had to dig for the SB-100 schematic, and the block diagrams and such I could find on short notice. (I don't have an SB-100 of my own, no need for the manuals.) Don't know if there are not better ones available, but from the schematic, and a quick poke at this thing, I would at least be checking the grid resistor for correct value. I wouldn't be surprised to find it almost open, seeing as how the voltages are very low down the chain from there.

And I'm probably way off. But that's OK, it's just one way to learn.

Oh, and as a matter of course I also tend to check tubes for element shorts and gassy conditions when I have to open up any tube-bearing critters.

I have an old (How else?) Navy issue tube tester, still has the salt-water seals on the cover, that will do anything up to radar transmitting tubes of the smaller variety. Testing a tube is not a big hardship. Sometimes finding the correct settings for a new(er) tube on this old(er) tube tester, now that can be a challenge. But with the specifications of the tube I can usually figure it out or get close enough to get a reasonable guess as on almost any common tube still in use.

Here's a problem for the inexperienced hams to solve. This is NOT a made
up problem, this problem actually occurred in my Heathkit SB-100. I know
this is not a Kenwood hybrid but it is a good problem to solve for those
studying vacuum tube theory.

Remember all those times you were told to take voltage measurements?
Well this is where all that comes "pays off"!!!

Symptom:
Receive audio is distorted
The S meter, after 3 to 4 minutes warm up, drifts below zero and remains
pegged hard against the meter peg
No signal, calibrator or strong receive signal brings the S meter above zero

Initial checks:
Meter zero pot is adjusted but no change, meter remains pegged below zero
Detuning the Preselector results in no change in the symptoms except the
audio level is lower
Adjusting the RF Gain control CCW causes the S meter to rise above zero
and when set fully CCW the meter pegs fully to the right.

Voltages were check for the receiver RF amp, receiver first mixer, first and second IF amplifiers. All 4 stages are directly or indirectly through resistors, connected to the same common receiver's AGC buss.

The following voltage measurements were taken and the results are as follows:

Receiver RF Amp and first receiver mixer's plate and screen voltages are good when compared to the manual's voltage chart
Receiver RF amp and first receiver mixer's grid voltages have decreased by .2VDC less than the voltage chart levels

First IF amplifier's plate and screen voltages were found to be significantly lower than the manual's voltage chart
First IF amplifier's grid voltage was found to be +1.5VDC

Second IF amplifier's plate and screen voltage were found to be lower than the manual's voltage chart
Second IF amplifier's grid voltage was +.8VDC

With all this information, what is the exact source of the problem?

Don't guess, use the information provided to solve the exact source of the problem then explain steps taken to fix all the problems.

Your choices are

1. Loss of operating bias to all 4 stages
2. First IF amp grid resistor had significantly increased in resistance value
3. RF gain control is very dirty resulting in improper operationg
4. Bias supply's filter capacitor has failed resulting in AC ripple on the bias buss
5. One of the tubes is gassy
6. Audio tube has a grid to screen short
7. Bad meter zero pot

Hi Wes,

Your "guess" answer that the grid resistor had changed values significantly, even become opened, is wrong. I will give you credit that you would have checked the tubes for gas in your Navy tube tester. I have no experience nor do I know how your Navy tube tester can test a tube for gas.

The only correct answer is 5, gassy tube.

The positive voltage, +1.5VDC. on the first IF amp's grid resulted "infected" as I called, the second IF amp's grid so it became +.8VDC AND decreased the grid voltage by .2VDC in the RX RF amp and first mixer stages. The reason the other 3 stages were effected is answered in my statement that all 4 stages were connected to the same AGC buss. The AGC and operating bias buss are "the same" buss!! Therefore, any positive voltage applied to the AGC or bias buss will be applied to the grids of all 4 stages and any other stages connected to this buss!!!

You can simulate this problem using a 1.5VDC AA battery with the positive lead connected to the grid of V3 (first IF amp) and the negative lead connected to the chassis in an HW-100, HW-101, SB-100/101/102. I'm sure there are other vacuum tube receivers/transceivers you can duplicate this problem in but the ones I mentioned, I am well aware of. Oh, have I duplicated this problem, after fixing it with a non-gassy tube, in the SB-100 using a 1.5VDC AA battery voltage applied to the grid of the first IF amp? YES I DID and the results are exactly what I expected them to be, everything the original problem had.

Oh, sorry, all the other answers are simply wrong.

Army, Navy, Marines, or Blue-Suit Air Force, they all show the same thing with a gassy tube. Grid current out of limits of course.

> 73
> Mike W5RKL

Likewise, Mike.

(And I knee the other three answers were bogus. Since there were problems in the grid current, it had to be either the resistor, or a bad tube. I just didn't follow it back well enough.)

I have found this diagram in the "files section" http://f1.grp.yahoofs.com/v1/1OctUrAC_aviYuKqxEOzF8YWGvA5NYaUx6IVu-dGQhSYn9uQwBPx5_4huNfkBpdn1jPIzZbGINak-MEcmlACq7su/KENWOOD%20TS-520S%20Power%20Connector%20Wiring.JPG

and need to know if what I'm looking at is the inside of the connector on the power cord or is it looking at the back of the radio or is it looking into the connector face into the female pins.
Sorry to have to ask such a simple question but my previous experience has been automotive connectors and they almost always give both female and male pin views (or component and connector).
Thanks for any clarification you can offer.

Look on the plug's solder terminals, each terminal should be marked with
a number. You may need a magnifying glass but I suspect you will see
each terminal IS marked with a number!

I meant to say you will see a number stamped on the plastic next to each
terminal on the solder terminal side of the plug. Match tho numberto the
schematic's wiring diagram and you should have no trouble wiring the plug.

Jason, you are referring to the same side of the plug I am. The pins are soldered on one side ONLY and that is the side where the pin numbers are stamped next to the pins. All he has to do is look and he will see the pin numbers.If he looks on the side where the pins are the Longest then he is looking at the wrong side.

Hi Terry
sorry I'm late but I've got to use the computer and do other tests

regards :

Yes these test points look like a small resistor. They are found with one end terminated on the board and the free end coiled to allow connecting a mini-grabber test lead. At TP-3 it is placed in series and has very low resistance maybe around 0.10 ohms and half of that is due to the resistance of the DMM test lead and clips.
It is good to measure VCO signal level at TP-3 because it tells you that the coax cable and connectors are good from the PLL board to the RF board. Approx 1.0 rms or 2.828 P-P VCO level is needed at RX and TX Mixers for good RX and TX performance. I have seen bad connections at the coax connectors at each end and one time the cable pulled off the connector.
Good idea to measure levels at D40 on PLL. If you have good readings at D40 then need to pull coax jumper off and re-seat it at each end.
I dont think the coax cable is the problem as you do have voltage at one end of VFO tuning range.
I looked at my notes and I see that the level at 0, 250, and 500 does not very much from Zero to 500. No more than 50 mv and usually less than this in the 10 to 15 mv range.
My lowest voltage levels were on 1.5mhz at approx 870mv rms or 2.46v P-P. On 20 meters approx 945mv or 2.67v P-P. On all other bands approx 1200 mv to 1300 mv or approx 3.5v P-P from zero to 500 VFO tuning range.
"

Unfortunately, I found that the tensions are very different so there must be something very obvious that I was wrong to measure

---
"
Lets talk about 20 meters (14mhz). Here is what I understand you found at Step 9. Let me know if this is correct.
DC voltages measured at TP-1 on PLL Board.
Frequencies measured at D40 on PLL board or at TP-3
VFO 0 = 3.70vdc @ 22.83mhz
VFO 250 = 4.50vdc @ 23.08mhz
VFO 500 = 5.73vdc @ 23.33mhz.
VCO output at TP-3 on RF board = 0.40 p-p at VFO 0-250-500 positions
Also, are you reporting you have approx 1.0 to 2.0 p-p rf volts at TP-3 on 1.5, 3.5 and 7.0 mhz. All other bands have 0 rf volts output at TP-3.
If you had a bad cable or connectors or solder connections you should not have any VCO output at TP-3 on some bands and not on others.
"Let me know if what I have stated here is correct.
"

Yes , as you say : here is correct, this is my situation

---
1. Is Conn 1 plugged in while taking the Step 9 voltages?
"
yes :the conn 1 in pll is plugged : the manual service not specify an unplugged action

---
"
2. Is the Digital Display blanked (off) for the bands where you have no VCO output voltage at TP-3?
"

no : at step 9 the Digital display is okay in all band : the digital display is blanked (off) only after step 10 , when unplug J1 , J5 and when i start to change the BPF-A ; after a first adjustment , in many bands , from 14.x to 29.x the Digital display is go off , even when I connected j1 , and for restore i've readjust in L14,T13,L15 and only after many attempts the display is go on in all band and all limits lower and upper;

==========

However, there is a small flea that's been bugging me for a while:
in step:

Step-3 0.3 +- 1dB
Step-5 1.0 +- 1dB
step-6 0.3 +- 1dB

is specified to control the voltages :

These voltages are Vrms or Vpp?
1) If are Vrms then I'm wrong because i interpreted these values as Vpp (not shoot me!)

if the manual service intends values in Vrms :

2) when the step-3 (as in step 5 but with a V = 1.0) says
0.3 +- 1dB what he means:
a)
-1 dB +1 dB
[0.891251, 1.12202] Vrms ->
[2.521, 3.174] Vpp
what is 0.3? an optimum value, a minimum value,an average ?

b)
0.3 -1 dB , 0.3 + 1 dB
[-0.591251, 1.42202] Vrms
-> [????, 4.022] Vpp
but lower value is negative : i must get the abs value?

3) when the step-6 says
0.3 +- 1dB what he means:
a)
-1 dB +1 dB
[0.891251, 1.12202] Vrms ->
[2.521, 3.174] Vpp
but the same step say :

"......if value outside specified limit adjust L19. L20 until voltage is 0.3 ...."
but then what does + / - 1 dB

maybe the problem is these values incorrect's for my rtx!

from a mathematical point of view it is not very clear which are the optimal values and the limits imposed

The mathematical expression:
x1 +- k
means:
[x1 - k, x1 + k]
but here I do not understand what you mean

(even less clear, but you've explained it well, what is the meaning of the target voltage in step 9)

What do you think?

Ugo

Ugo:

Maybe we should start a new thread as this is getting long or take off the forum as not sure much interest in the TS-830 PLL? I am in no hurry and no pressure on you. You do this at your own pace. Sometimes it is good to back track and repeat steps.

It appears to me that you are starting at Step 1 in the Service Manual and doing a complete alignment for the first time. If this is correct it will take time to understand the steps and absent some key test gear alternate methods to accomplish the step or to perhaps skip the step.If you get to a point where you cannot perform the step we can discuss that.

The voltage levels in the Service Manual are RMS taken by a RF probe and VTVM or a RF Millivoltmeter.

For example, at Step 3 you are measuring and adjusting the RF output voltage level of the Carrier Oscillator. The spec says it should be 0.3v +/- 1dB. This means they are looking for 300mv, but the radio will perform to specification if the voltage is 1dB higher than 300mv or 1 dB lower than 300mv. You could say that 300mv is the optimum level, but running with the level within the +/- 1 dB tolerance will not result in measurable receiver or transmitter performance decline.

This means the Carrier Osc level should be 267mv to 377mv by my math. So using your O-scope it would be a low of 0.755 p-p to a high of 1.066 p-p volts.

Step 5 states 1.0v +/- 1dB. I interpret that to mean 0.890v to 1.122v rms. Using your O-scope means 2.52 p-p to 3.17 p-p. So 2.83 p-p would be "optimum", but 2.52 to 3.17 is OK.

Maybe it would be better to say these are "Target" values and not "Optimum".values. If a value was critical they would tighten up the +/- dB tolerance.

Yes Step 9 has to be performed with Conn1 and Conn 5 plugged in.

Suggest you check my math as always easy for a mistake or a typo.

I will read and study the rest of your response.

sorry I'm late but I've got to use the computer and do other tests

regards :

Yes these test points look like a small resistor. They are found with one end terminated on the board and the free end coiled to allow connecting a mini-grabber test lead. At TP-3 it is placed in series and has very low resistance maybe around 0.10 ohms and half of that is

due to the resistance of the DMM test lead and clips.
It is good to measure VCO signal level at TP-3 because it tells you that the coax cable and connectors are good from the PLL board to the RF board. Approx 1.0 rms or 2.828 P-P VCO level is needed at RX and TX Mixers for good RX and TX performance. I have seen bad connections at the coax connectors at each end and one time the cable pulled off the connector.
Good idea to measure levels at D40 on PLL. If you have good readings at D40 then need to pull coax jumper off and re-seat it at each end.
I dont think the coax cable is the problem as you do have voltage at one end of VFO tuning range.
I looked at my notes and I see that the level at 0, 250, and 500 does not very much from Zero to 500. No more than 50 mv and usually less than this in the 10 to 15 mv range.
My lowest voltage levels were on 1.5mhz at approx 870mv rms or 2.46v P-P. On 20 meters approx 945mv or 2.67v P-P. On all other bands approx 1200 mv to 1300 mv or approx 3.5v P-P from zero to 500 VFO tuning range.
"

Unfortunately, I found that the tensions are very different so there must be something very obvious that I was wrong to measure

---
"
Lets talk about 20 meters (14mhz). Here is what I understand you found at Step 9. Let me know if this is correct.
DC voltages measured at TP-1 on PLL Board.
Frequencies measured at D40 on PLL board or at TP-3
VFO 0 = 3.70vdc @ 22.83mhz
VFO 250 = 4.50vdc @ 23.08mhz
VFO 500 = 5.73vdc @ 23.33mhz.
VCO output at TP-3 on RF board = 0.40 p-p at VFO 0-250-500 positions
Also, are you reporting you have approx 1.0 to 2.0 p-p rf volts at TP-3 on 1.5, 3.5 and 7.0 mhz. All other bands have 0 rf volts output at TP-3.
If you had a bad cable or connectors or solder connections you should not have any VCO output at TP-3 on some bands and not on others.
"Let me know if what I have stated here is correct.
"

Yes , as you say : here is correct, this is my situation

---
1. Is Conn 1 plugged in while taking the Step 9 voltages?
"
yes :the conn 1 in pll is plugged : the manual service not specify an unplugged action

---
"
2. Is the Digital Display blanked (off) for the bands where you have no VCO output voltage at TP-3?
"

no : at step 9 the Digital display is okay in all band : the digital display is blanked (off) only after step 10 , when unplug J1 , J5 and when i start to change the BPF-A ; after a first adjustment , in many bands , from 14.x to 29.x the Digital display is go off , even

when I connected j1 , and for restore i've readjust in L14,T13,L15 and only after many attempts the display is go on in all band and all limits lower and upper;

==========

However, there is a small flea that's been bugging me for a while:
in step:

Step-3 0.3 +- 1dB
Step-5 1.0 +- 1dB
step-6 0.3 +- 1dB

is specified to control the voltages :

These voltages are Vrms or Vpp?
1) If are Vrms then I'm wrong because i interpreted these values as Vpp (not shoot me!)

if the manual service intends values in Vrms :

2) when the step-3 (as in step 5 but with a V = 1.0) says
0.3 +- 1dB what he means:
a)
-1 dB +1 dB
[0.891251, 1.12202] Vrms ->
[2.521, 3.174] Vpp
what is 0.3? an optimum value, a minimum value,an average ?

b)
0.3 -1 dB , 0.3 + 1 dB
[-0.591251, 1.42202] Vrms
-> [????, 4.022] Vpp
but lower value is negative : i must get the abs value?

3) when the step-6 says
0.3 +- 1dB what he means:
a)
-1 dB +1 dB
[0.891251, 1.12202] Vrms ->
[2.521, 3.174] Vpp
but the same step say :
".....if value outside specified limit adjust L19. L20 until voltage is 0.3 ...."
but then what does + / - 1 dB

maybe the problem is these values incorrect's for my rtx!

from a mathematical point of view it is not very clear which are the optimal values and the limits imposed

The mathematical expression:
x1 +- k
means:
[x1 - k, x1 + k]
but here I do not understand what you mean

(even less clear, but you've explained it well, what is the meaning of the target voltage in step 9)

What do you think?

Ugo

44437. Trouble with external VFO-820; same relay as in TS-820?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-10 14:39:23 UTC

Topic: 44437 Message: 44437

I'm having trouble with an external VFO-820 - when I plug it into my TS-820, it doesn't work properly in that it won't change frequencies and won't really do much of anything. It looks like it should be working - the lights come on, etc. - but I would think more than likely that it is a relay problem, but I'm open to suggestions.

I took the relay out and cleaned the contacts on the bottom, but I haven't opened the relay itself up to clean inside. One of my friends here, Jimmy Lamanteer, mentioned that I could carefully open the plastic top on the relay and try to clean the contacts inside with a little DeOxit on a business card.

If that doesn't work, is this relay the same as the one that goes in the TS-820? If so I could just order an OMRON relay and be fine, right?

Barry
KK4RXN
Jeremiah 29:11-13 / John 3:16

P. S. The TS-820 is still kicking along just great - I took it to the beach when I was on vacation last week and easily made contacts into Germany, Hungary, and all over the US on a speaker wire dipole that I had tied to a 20' crappie pole on the vacation house balcony.

Ugo:

If you are going thru the complete TS830 alignment using the service manual there is one more thing to remember. Any step that tells you to inject a RF signal they will list the signal level in dB. This dB level is not the American standard that we typically use. This can confuse you.

For example if you look at Step 15 where you are aligning the receiver IF amp transformers they tell you to inject 1.9mhz at 40dB. This means you inject 50.0uv or a -73dBm signal and not 100uv. Be careful looking at some conversion charts on the web as they are not based on correct reference.

The Kenwood Japanese SG 0dB = American SG 0.50uv = -113dBm

With 0dB = 0.50uv then for each 6dB step the voltage will double. So 6dB = 1.0uv, 12dB = 2.0uv ....40dB = 50.0uv and so on.

Microvolts (uv) and dBm output levels are more typically available on the common signal generators we use here (HP8640B, Wavetek 3002, HP 606, URM 25B, BK E200D etc) and not dB.

If you do not have a Rf sig gen with a calibrated step attenuator we can discuss options off the forum.

Hey guys,

I just got into amateur radio last month. I got my first HF rig at an estate sale for an old ham who passed away. I got the TS-520. The amateurs at the sale said the guy took really good care of his stuff and that this rig was recently serviced. I took it home and began to set it up.

I am operating on 40 meters with a dipole. All I have is this rig, a SWR meter, and the dipole, no other equipment for HF.

I ran through the tuning procedure in the Kenwood manual, I followed it exactly and everything went fine up to dipping the plate. The needle shows 60 ma, In order for ALC to peak, CAR needs to be set at 1.5 (anything higher and the needle pegs), and the plate reading is 80 ma, but will not dip when I turn the plate dial (which is centered on the band as per the instructions). I have also followed the tuning instructions by Ken, K4EAA and the same result happens.

I do not know for sure what my antenna's SWR is, when I attempt to use my SWR meter, it will not calibrate. I know the meter works, so I was concerned is may be an issue with the TS-520.

I have looked through the groups past posts, as well as Google, and I can't seem to find an answer to my problem. This post is the result of at least 3 days of failed research. Any help would be greatly appreciated. I can tune stations in just fine on 40 meters, but they just can't hear me (which is understandable for this situation).

Thank you guys in advance,

Jason, K7BOG

Jason,

Before you do anything else you should invest in a 50 ohm dummy load. Sometimes you can find a Heathkit Cantenna dummy load at swapmeets or estate sales. I think MFJ makes a clone of the Heathkit. These are rated at 1KW for about 10 seconds with the oil in them. I would get one rated at least 300W for use with the TS-520.

Using the dummy load has two benefits. One you won't be transmitting on the air while trying to fix a transmitter problem. Second, the load seen by the transmitter will be known and correct.

73,

Bill

Quick question for clarity's sake. With what (coax or balanced
feedline) are you feeding your dipole? And how high up is it, just for
grins.

The reason your meter won't calibrate nor the 520 transmit is very
likely contained right here. It's probably NOT the radio.

Great idea. But don't neglect the "building one" option.

You can get a bulkhead connector, a small tube of silicone, an empty quart paint can, some mineral oil, and a hand-full of resistors, for pretty cheap.

As in less than ten bucks cheap. I know because I've got one that will handle at least 500W, nearly indefinitely, right here and that's about what I have in it.

Took some soldering and a little work with a pencil and calculator (to get almost 100 resistors to come out to 50 ohms in a series-parallel combination), a drill and a ream for the hole in the lid, but it was cheap, and it works just fine.

Some times, ten dollars is even too much. I know all too well. (Stuck with an over-priced, still-busted 520SE, but with a perfectly-working -50 mike, and even the DG-5 and all the cables to go with it.... Got it down to three more wires to trace. I hope.)

You need to advance the carrier control very carefully until; the plate current Ip Just starts to rise with the radio transmitting in the Tune Mode.Then start turning the drive control until you get a peak reading. Does this happen? A sudden jump in Ip indicates a dirty control or something more serious.
Good luck

I am playing with a TS-520S I bought at the Salvation Army a few years back. I had played with it for a while back then, but walked away from it. The receiver works 100%. However, I am only getting about 10W out on transmit for both CW and SSB. The strange thing is that I get almost no signal unless I back the carrier knob all the way counter clock wise to zero, and I finally get about 10w for CW. All other settings produce almost no output. The carrier knob doesn't seem to do anything for SSB on this radio. Again only about 10W out. Could this mean the driver tube is flat?

Any suggestions? I would love to get this old gal running 100% again.

Chris:

The CAR pot has nothing to do with SSB mode in any KW hybrid radio. The CAR pot is used to forward bias the Balanced Modulator ring diodes in CW mode to produce a carrier output. In SSB the audio from the mic and the carrier oscillator mix in the Balanced Mod to produce a DSBSC signal.

Typical CAR pot levels in Tune or CW mode on a TS-520/520S with a good Driver stage is approx 2 (0900) for full scale ALC black box indication and 5 (1200) for FSD or full scale deflection of the meter.

Have you set the zero signal resting plate current to 60ma? If so, proceed to following test.

Easy test of the Driver stage is as follows:
1. SG switch off
2. Power and heaters on
3. Mode switch CW, Drive Control at 1200, VFO 200
4. Meter in ALC position
5. Car pot at 1200
6. Flip to Send and Peak the Drive control. If meter pegs full scale back Car pot level down to just get meter indicator off the peg.
7. Dont leave rig keyed for more than a few seconds. Leave it keyed long enough to make sure that the ALC indication doesnt slowly fall off of FSD. This most commonly may occur on 10 meters. If it does, it is time to replace the 12BY7A.
8. Repeat above steps on all bands.
9. With good driver stage should be able to get FSD on all bands with exception of perhaps 10 meters. On my 520 I can get full scale ALC deflection on 29mhz with Car pot advanced to 6.5 (1330). All other bands no more than 1200.

If you cannot get FSD with Car pot at approx 1200 then easy to try a new 12BY7A as a first step to resolve 10 watts output.

If Driver stage passes above test can be many reasons for low output.
1. Soft finals
2. Bad PA cage plate choke
3. Low finals anode and screen grid voltages
4. Usually band switch contacts are not the problem if low output occurs on all bands.

Do the Driver tube test and report back results. Also, do you have any means to measure RF drive levels? O-scope, RF millivolt meter, RF probe/VTVM? Easiest way to find reason for low RF output is to perform TX Level Diagram in the Service Manual.

44449. Kenwood Hybrid Net Update (September 10, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-11 01:53:16 UTC
From: Mark Gilger
Topic: 44449 Message: 44449

The Saturday□s net on 40 meter we had 11 stations checking in under good band conditions, although there was a contest on that was giving us a headache. There were 1 new check-ins, K4TFJ. Out of those, there was:

```
3 running TS-520(x)
3 running TS-530(x)
1 running TS-820(x)
0 running TS-830S
0 running TS-900

I was running my TS-940s. The rest were running
non hybrids of one model or another.
```

The Sunday□s net was run by Jimmy, WB2KNR on 20 meter. He had 20 stations checking in under good band conditions. He had 11 new check ins, KB0HAS, KJ4BT, KJ3Q, KD0PTM, K9ILL, N7GOD, N4JK, KC9RTX, N5EXK, WU7G, and KC9QVV. Out of those, there was:

```
4 running TS-520(x)
1 running TS-530(x)
3 running TS-820(x)
4 running TS-830S

The rest were running non hybrids of one model or another.
```

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

```
If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.
```

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins

November 2012, Saturday☐s, net total = 47, Sundays total = 20
December 2012, Saturday☐s, net total = 74, Sunday☐s total = 70
January 2013, Saturday☐s, net total = 93, Sunday☐s total = 87
February 2013, Saturday☐s net total = 103, Sundays total = 87
March 2013, Saturday☐s, net total = 112, Sunday☐s total =39
April 2013, Saturday☐s net total = 52, Sunday☐s total = 29
May 2013, Saturday☐s net total = 45, Sunday☐s total = 50
June 2013, Saturday☐s net total = 30, Sunday☐s total = 27
July 2013, Saturday☐s net total = 63, Sunday☐s total = 41
August 2013, Saturday☐s net total = 82, Sunday☐s total = 50
September 2013, Saturday☐s net total = 11, Sunday☐s total = 20 (Month to date)

Hi Terry

Regards :

"
..... dB level is not the American standard that we typically use. This can confuse you. For example if you look at Step 15 where you are aligning the receiver IF amp transformers they tell you to inject 1.9mhz at 40dB. This means you inject 50.0uv or a -73dBm signal and not 100uv. Be careful looking at some conversion charts on the web as they are not based on correct reference.
The Kenwood Japanese SG 0dB = American SG 0.50uv = -113dBm
With 0dB = 0.50uv then for each 6dB step the voltage will double. So 6dB = 1.0uv, 12dB = 2.0uv ....40dB = 50.0uv and so on.
Microvolts (uv) and dBm output levels are more typically available on the common signal generators we use here (HP8640B, Wavetek 3002, HP 606, URM 25B, BK E200D etc) and not dB. If you do not have a Rf sig gen with a calibrated step attenuator we can discuss options off the forum.
"

thank you very much:

like you said I had misread but since I do not have a generator and accurate output voltages from the old Mial-150 the rule with a potentiometer, checking them oscilloscope, what you've told me is useful, very useful;

Well, at this point, as you said I think it is appropriate to close the thread but not without making a small conclusion:
the sweeper is almost essential, and perhaps cheapest way can be to use, as you suggested, a dds which, in my case will be controlled
by Arduino, allowing you to brush the various freq:
In my economic situation , given the low expense of a board dds with AD9850 and the availability of an arduino v2, does not cost much to try to make a sweeper also because I found many examples of interface between arduino and that card, and drive the whole PC for graphics and setup (if it does work no problem to publish hardware and software)

Ugo

Chris where in the manual does it tell you to use the Ip meter position to peak the Drive control? Disregard that kind of advise at this stage of your knowledge and experience.

You did not answer if you have set the resting plate currrent to 60ma in SSB mode with mic gain turned down. Were you able to do this?

I am 500% certain you dont want meter in Ip position. New folks are best served following the instructions.

When I told you to place meter in ALC and peak the Drive control that is what I meant. Not Ip.

If we are to help you it is important that you follow instructions and report back findings. So one last time from me:
1. Power on
2. Heaters on
3. Meter to ALC
4. Car Level pot at 1200
5. Drive Control at 1200
6. VFO 200 (need it in mid range so that the ALC peak will occur near 1200)
7. Mode switch Tune position
8. Band switch (repeat the test on each band)
9. Flip to Send and peak the Drive control for maximum ALC indication
10. If meter pegs back down Car Pot
11. If no meter indication increase CAR pot full CW and repeat

If you get no ALC indication on any band with Car pot full CW then report back.

Terry K9TW.

5. Car pot at 1200
6. Flip to Send and Peak the Drive control. If meter pegs full scale back Car pot level down to just get meter indicator off the peg.
I get nothing here. I have to turn the Screen Grid back on to get anything.

7. Dont leave rig keyed for more than a few seconds. Leave it keyed long enough to make sure that the ALC indication doesnt slowly fall off of FSD. This most commonly may occur on 10 meters. If it does, it is time to replace the 12BY7A.

I am not showing any deflection, are you sure the meter is not supposed to be in plate current mode?

8. Repeat above steps on all bands.
9. With good driver stage should be able to get FSD on all bands with exception of perhaps 10 meters. On my 520 I can get full scale ALC deflection on 29mhz with Car pot advanced to 6.5 (1330). All other bands no more than 1200.

If you cannot get FSD with Car pot at approx 1200 then easy to try a new 12BY7A as a first step to resolve 10 watts output.

Ok, off to the junk box.

If Driver stage passes above test can be many reasons for low output.
1. Soft finals
2. Bad PA cage plate choke
3. Low finals anode and screen grid voltages
4. Usually band switch contacts are not the problem if low output occurs on all bands.

Do the Driver tube test and report back results. Also, do you have any means to measure RF drive levels? O-scope, RF millivolt meter, RF probe/VTVM? Easiest way to find reason for low RF output is to perform TX Level Diagram in the Service Manual.

I have a scope, but not the other RF meters.

Terry K9TW

Thanks, Terry

Ugo:

In old days I had many LC type RF sig gens (Heath, Knight, Eico etc). These were certainly better than no sig gen and fine for signal injecting/tracing for troubleshooting but not good for alignment/calibration work. I have had to use O-scope to measure the Rf output voltage of the sig gen.

Remember if you homebrew the DDS sweep gen to include a sync output circuit (usually saw tooth) to provide a signal for the scopes external trigger input. This will be needed for stable display.

Lastly will need a means of generating Marker signals.

Might want to seach the Web for DDS sweep gen designs or kits?

It takes same relay as the Aux relay in the radio. However would be pretty rare for the relay to be bad.

Are you saying it has an open closing coil or do you believe it has bad contacts?

You can try swapping with relay from the rig.

The contacts handle very little current so should last a life time. You can remove the plastic cover and wet some strips of copy paper with Deoxit and pull them thru the NO and NC contacts. Apply gentle pressure on the armature as you pull the wetted paper thru the contacts.

Kens Electronics in Kalamazoo Mich carries a NOS sub that works well.

Topic: 44459 Message: 44459

I'm improving my videosusing a different camera (Logitech C920 webcam) along with a new White Board. I made 2 simple Ohms Law videos, one is a simple Ohms Law test and the other contains the answers to, along with explanations, the Ohms Law test.

If you are interested, send me an email and I'll send the test video to you. You can view the videos using Windows Media Player. Provide your answers to include how you arrivedat your answers. Do NOT guess!!! Once I receive your answers I'll send you the video containing the answers and explanationson how to achieve the correct answers.

For those wondering if I would just upload them to Youtube, the answer is "No", at least not at this point.

Topic: 44459 Message: 44460

Hey y'all,

Has anyone replaced a TS-830S's mixer diodes D20-24 with Schottky devices? If so, what were the effects?

My 830 exhibits a hint of distortion on strong voice peaks, unlike my clean-as-a-whistle TS-530S. I'm wondering if improved diodes might help.

Oh -- one other question. Does anyone know of a workable replacement for the SM-200's seemingly unobtainable 75ARB31 CRT (or a source of this elusive item that I may have overlooked)?

Thanks and 73,

Craig
W3CRR

44462. TS-820 - tapping into the final stage

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-11 18:24:48 UTC

Topic: 44462 Message: 44462

I am considering working on a modification to my radio, but I need some guidance from the experts as I try to come up with a plan. ;-)

My goal: be able to connect the output of a QRP radio into the final stage of the TS-820 to use it as an amplifier. I assume this is possible, but please correct me if I'm wrong.

Things I think I need to look into:
- Where in the TS-820 signal paths I need to break connections and add some type of switch to choose which signal to feed into the final stage (TS-820 or external).
- Figure out what's the input power going into the final stage in the TS-820, so I try to match it (or stay below it) with the QRP radio.
Any hints on what things I need to watch out for while trying to figure out how to do this will be greatly appreciated. :-)

Thanks!

Chris:

I tried to respond but have not seen it yet so not sure what happened. I dont like this new format. Hard to teach old dog new tricks/.

So let me restate to make sure I fully understand.

You are telling me that you had the SG switch off, the Heaters on, in CW mode, Meter in ALC, the CAR level pot full CW or at minimum no less than at 1200 or No 5 position. When you flip to send and peak the Drive control thru its complete range that you get no ALC indication on any band. If that is true then most likely problem is:

1. Bad 12BY7A driver tube or bad dc voltages to it or bad solder connections at tube socket.
2. Bad/dirty contacts on Aux relay that switches the ALC bus voltage
3. A bad meter position switch contacts (not very common).

I would start by replacing the 12BY7A driver tube. Make sure rig is unplugged and let it set awhile to ensure voltage discharged off HV caps. Remove rig top cover to access tube on the RF board. Sometimes the ground strap can be galled and bonded to the metal shield. There is a full length split on the shield. Use a thin flat blade screw driver to spread the split. Carefully work the shield can off so you do not break the ground strap that is sandwiched between the glass envelope and metal can. When replacing the shield make sure the ground strap is placed back between the shield and the tube.

Here is where you need an RF Probe and VTVM. In 10 minutes you could measure the RF drive voltage at the control grids of the 6146 finals to see if you have RF drive greater than approx 39rms volts. Should be close to 46rms volts for full scale ALC deflection. If you are experienced with O-scope could use it as well. RF probe and VTVM are a must have if to service own Hybrid.

If new Driver tube doesnt help then try cleaning the Aux relay. Come back for the procedure for that.

In case you are interested for the above test to work you need the following:
1. Good 6146 final tubes. By good I mean good filament so there is cathode emission.
2. Good negative dc operating bias on the control grids of the finals. By good I mean voltage on control grids must switch from approx -100vdc cut off bias to approx -55vdc operating bias when you flip to Send. This is occurring as you stated you are able to set resting plate current to 60ma.
3. Good RF drive voltage at the control grids of the 6146 finals. By good I mean approx 46rms rf volts. 46 x 1.414 = 65 peak rf volts. +65 and -55 = approx +10 volts on positive peak of the drive envelope. This causes control grid to be positive with respect to the cathode and approx 40ua of grid current.

When the control grid of the 6146 final tubes becomes positive with respect to the cathode grid current will flow. When grid current flows the ALC amp transistor senses it and reduces the ALC bus voltage and reduces the RF drive. When the ALC bus voltage is reduced from its nominal 3.2vdc RF-1 level the ALC meter circuit sees this and drives the meter up scale. So with any hint of grid current the ALC meter should move up scale. At approx 40ua of grid current meter should be full scale.

If the Driver tube is soft could have insufficient RF voltage swing at 6146 control grids to overcome the -55vdc bias offset. For example if Driver tube is only capable of 39rms volts then 39 x 1.414 = 55 peak volts. So if RF drive is swinging the control grid to +55 volts on positive going peak of the drive envelope then +55 and -55 means Zero difference voltage and the control grid is not positive with respect to the cathode and there will be no grid current and no ALC indication.

Yes, you have understood me correctly I did the test 100% per your
instruction. I also did the test as if I was following the tuning
procedure to peak the driver as per the manual. I did this in TUN mode.
Every single band showed no deflection when the CAR was at 5 and also at
10 (fully CW). I will try to get a hold of a 12BY7A and report back.

Thank you for the flow chart below.

Two more questions. Why would it only put out power in CW when the CAR is fully CCW (0 position)? If I increase it at all I loose all power to the antenna. At full CCW I get 10W out. This seems strange to me. However, under NO conditions do I get an ALC deflection (in TUN or CW). I have not messed with the ALC in SSB. However, I only get about 10W out in SSB too. Audio is also a bit on the crappy side. I suppose loss in linearity of the driver tube could explain the bad audio.

Can I use my modern DVM in place of a VTVM? I might have an oldy at my parent's house if they have not tossed it.

Thanks,
Chris

I am using about 25 feet of RG-8X, 50ohm. The antenna is in a pseudo V formation on my roof (one leg is coming down and is attached to my wooden fence, the other is sloping along the side of my roof, with the center of the dipole attached to my satellite dish mount, maybe 20-25 feet off of the ground.

--- In ts-520_820_530_830@yahoogroups.com, <wwill@...> wrote:

> I am operating on 40 meters with a dipole. All I have is this rig, a SWR

Quick question for clarity's sake. With what (coax or balanced
feedline) are you feeding your dipole? And how high up is it, just for
grins.

> I do not know for sure what my antenna's SWR is, when I attempt to use
> my SWR meter, it will not calibrate. I know the meter works, so I was
> concerned is may be an issue with the TS-520.

The reason your meter won't calibrate nor the 520 transmit is very
likely contained right here. It's probably NOT the radio.

Thanks to all for the responses. If I had a brain I would have figured it out as the pin numbers get the wires soldered to them and the numbers are right next to the pins, DUH. thanks again, Jerry K4GEW

--- In ts-520_820_530_830@yahoogroups.com, <w5rkl@...> wrote:

Jason, you are referring to the same side of the plug I am. The pins are soldered on one side ONLY and that is the side where the pin numbers are stamped next to the pins. All he has to do is look and he will see the pin numbers. If he looks on the side where the pins are the Longest then he is looking at the wrong side.

On 9/9/2013 11:58 AM, jason.bogstie@... wrote:

You should be looking at the pins on the inside of the connector. I wired mine backwards on the first attempt, I didn't burn anything up, the cable just didn't work. I ended up having to wire it twice.

-Jason, K7BOG

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I have found this diagram in the "files section" http://f1.grp.yahoofs.com/v1/1OctUrAC_aviYuKqxEOzF8YWGvA5NYaUx6IVu-dGQhSYn9uQwBPx5_4huNfkBpdn1jPIzZbGINak-MEcmlACq7su/KENWOOD%20TS-520S%20Power%20Connector%20Wiring.JPG

and need to know if what I'm looking at is the inside of the connector on the power cord or is it looking at the back of the radio or is it looking into the connector face into the female pins.
Sorry to have to ask such a simple question but my previous experience has been automotive connectors and they almost always give both female and male pin views (or component and connector).
Thanks for any clarification you can offer.

I do not know why Car Pot is behaving this way. Perhaps you have bad Balanced Modulator ring diodes or the carrier null is severely mis-adjusted? I would fix ALC indication/rf drive first and then see if there is a relationship.

The Car Level Pot works with the Balanced Modulator to produce a CW carrier. The Balanced Modulator is a Mixer. Car pot takes 9vdc and supplies it thru voltage divider to provide a variable 0.1vdc to 0.7vdc to forward bias the ring diodes. When these diode pairs are turned by this variable bias voltage from the Car Level Pot it unbalances the modulator and produces a carrier at the output. You adjust the output power in CW mode with the Car Level pot. It has no efffect in SSB mode.

When you say you are getting 10 watts output in SSB mode are you saying when you key the mic in SSB with mic gain turned all the way down you are getting out 10 watts? OR

Are you saying while modulating the rig in SSB mode (speaking into the microphone with the mic gain turned up to approx 1200) that you only see about 10 watts on voice peaks?

These are two very different things. 10 watts on voice peaks is a little low but it depends on your mic, the mic gain setting, how you are talking in to it and a little with the ballistic characteristics of your wattmeter.

If it is the former then the Balanced Modulator carrier null/balance is probably out of adjustment assuming no problem with the ring diodes. You will need to adjust TC-1 and VR-2 on the Generator board to null and balance the carrier between LSB and USB. Will need RF probe and VTVM/DMM or O-scope to do this. We can help you perform this step. Another way to do it is with a separate receiver sitting near the 520 but not as sensitive, but probably OK at this point to get it close.

If it is the later then with rig loaded to 100 watts output it is normal to see peaks of no more than 25 to 30 watts maximum on an average reading wattmeter as you modulate the rig. If you had ALC indication would tell you to adjust mic gain to keep ALC indication within middle of the black rectangular box. Your manual will tell you to keep the peaks within the upper limit of the range. This is to prevent splatter to adjacent frequencies.

With the rig in LSB or USB you should be able to key the mic or flip to send and have no RF output power until you speak in the Mic. The Car Level pot has nothing to do with this. It can be set anywhere and have no effect on SSB power output.

When you say your audio is distorted are you saying your transmit audio or receive audio? If transmit then I would perform the carrier null/balance as a first step.

Yes you can use a DMM but it is not as good for peaking and nulling as an analog meter is. It will work if that is what you have. Also, depending on your DMM it may not be 10meg input and not good for much more than measuring things like dc power supply voltages and some of the tube dc voltages. Not good for getting on grids of tubes and AGC/ALC bus work. A cheap Harbor Freight has an input Z of under 1 meg and some of the Lowes/Sears/Home Depot are around 2meg. They are for electricians and not electronic work.

Chris:

I tried to respond but have not seen it yet so not sure what happened. I dont like this new format. Hard to teach old dog new tricks/.

So let me restate to make sure I fully understand.

You are telling me that you had the SG switch off, the Heaters on, in CW mode, Meter in ALC, the CAR level pot full CW or at minimum no less than at 1200 or No 5 position. When you flip to s! end and peak the Drive control thru its complete range that you get no ALC indication on any band. If that is true then most likely problem is:

Yes, you have understood me correctly I did the test 100% per your instruction. I also did the test as if I was following the tuning procedure to peak the driver as per the manual. I did this in TUN mode. Every single band showed no deflection when the CAR was at 5 and also at 10 (fully CW). I will try to get a hold of a 12BY7A and report back.

Thank you for the flow chart below.

1. Bad 12BY7A driver tube or bad dc voltages to it or bad solder connections at tube socket.

2. Bad/dirty contacts on Aux relay that switches the ALC bus voltage
3. A bad meter position switch contacts (not very common).

I would start by replacing the 12BY7A driver tube. Make sure rig is unplugged and let it set awhile to ensure voltage discharged off HV caps. Remove rig top cover to access tube on the RF board. Sometimes the ground strap can be galled and bonded to the metal shield. There is a full length split on the shield. Use a thin flat blade screw driver to spread the split. Carefully work the shield can off so you do not break the ground strap that is sandwiched between the glass envelope and metal can. When replacing the shield make sure the ground strap is placed back between the shield and the tube.

Here is where you need an RF Probe and VTVM. In 10 minutes you could measure the RF drive voltage at the control grids of the 6146 finals to see if you have RF drive greater than approx 39rms volts. Should be close to 46rms volts for full scale ALC deflection. If you are experienced with O-scope could use it as well. RF probe and VTVM are a must have if to service own Hybrid.

If new Driver tube doesnt help then try cleaning the Aux relay. Come back for the procedure for that.

In case you are interested for the above test to work you need the following:
1. Good 6146 final tubes. By good I mean good filament so there is cathode emission.
2. Good negative dc operating bias on the control grids of the finals. By good I mean voltage on control grids must switch from approx -100vdc cut off bias to approx -55vdc operating bias when you flip to Send. This is occurring as you stated you are able to set resting plate current to 60ma.

3. Good RF drive voltage at the control grids of the 6146 finals. By good I mean approx 46rms rf volts. 46 x 1.414 = 65 peak rf volts. +65 and -55 = approx +10 volts on positive peak of the drive envelope. This causes control grid to be positive with respect to the cathode and ! approx 40ua of grid current.

When the control grid of the 6146 final tubes becomes positive with respect to the cathode grid current will flow. When grid current flows the ALC amp transistor senses it and reduces the ALC bus voltage and reduces the RF drive. When the ALC bus voltage is reduced from its nominal 3.2vdc RF-1 level the ALC meter circuit sees this and drives the meter up scale. So with any hint of grid current the ALC meter should move up scale. At approx 40ua of grid current meter should be full scale.

If the Driver tube is soft could have insufficient RF voltage swing at 6146 control grids to overcome the -55vdc bias offset. For example if Driver tube is only capable of 39rms volts then 39 x 1.414 = 55 peak volts. So if RF drive is swinging the control grid to +55 volts on positive going peak of the drive envelope then +55 and -55 means Zero difference voltage and the control grid is not positive with respect to the cathode and there will be no grid current and no ALC indication.

Cesar:

Class AB-1 doesnt really take RF drive power. Since there is no grid current can be no power consumed. Only RF voltage swing is required. However, there are rf losses from charge and discharge of the inter-electrode capacitance of the 6146 tubes at an rf rate and from cathode/heater lead inductance path. So in practice the 12BY7A driver tube does supply approx 2.0 to 2.5 watts output power to the 6146 control grid circuit.

You can estimate the output power by calculating the plate current and the dc input power and then assuming an efficiency factor for a Class A rf amplifier. To do this look at your schematic and total up the resistance in the cathode lead to ground or just measure it. Then use the cathode voltage in Tx mode listed on the schematic or measure it and use I = E/R. Some schematics show 0 cathode volts in Tx which is of course wrong.

For example for a TS830 the cathode resistance is 168 ohms and cathode voltage is 4.6vdc. Plate current (ignoring small amount of screen grid current) I = 4.6/168 = 27ma. Plate voltage = 297vdc so Dc input power is P= 297 x .027 = 8 watts. Assume Class A amplifier efficiency = 25% then 8 x .25 = 2.0 watts. If efficiency was 30% then output power = 8 x .30 = 2.4 watts.

So approx Dc input power of the KW hybrid 12BY7A Driver tube is 8 watts and approx RF output power is 2.0 to 2.5 watts.

What the control grid of the 6146 looks like to the Driver plate circuit is a complex Z. It is really Admittance that can be looked at as a capacitor and resistor in parallel and shunted from grid to cathode. It is not easy to calculate and it varies. With no grid current the Z is essentially infinite and with grid current it can be around 1000 ohms or so.

I have played around with lifting the DRV lead off the 6146 control grids and placing a carbon resistor dummy load to chassis ground and measuring the RF voltage across it. From around 1000 to 2000 ohms can get close to the same level of RF voltage as with DRV terminated on the 6146 grids. Using a 1000 ohm carbon resistor to simulate what the Driver tube tank circuit sees isnt exactly correct and in fact may de-tune the Q of the tank.

For high power Class AB1 linear amps it is common to place a 100 ohm or so high wattage swamping resistor from grid to cathode to provide a constant impedance for the driver stage to look at so wont have distortion. We dont do that with our hybrids. We rely on a parallel resonant tank circuit at output of the Driver tube to smooth out the impedance variations under SSB modulation and very small amounts of grid current to ensure we will not have a lot of distortion and IMD generation.

You can approximate the impedance of the 6146 control grids by this formula:
Rg = (Eg max) squared/ 2 x Pd. Where Rg is the grid impedance, Eg is the peak RF drive voltage, and Pd is the peak drive power.

Here is calc for TS-830 using 47rms volts of rf grid drive at 6146 control grids (measured at 100 watts output power) 47 x 1.414 = 66 peak rf volts:

Rg = (66)squared /2 x 2 = 4356/4 = 1089 ohms

So 6146 control grids look approx like a 1100 ohm resistor with 47volts drive and -60vdc operating bias. This means if you terminate the 12BY7A DRV lead with approx 1100 ohms to ground the tube will deliver approx 2 watts.

I call these back of envelope calcs.

I suspect your QRP rig would like to look at 50 ohms so you would most likely need a broad band transformer at the control grids to get the match from 1100 ohms to approx 50 ohms? Could wind a toroid transformer or buy transformer from Mini-circuits. I wont go into the impedance ratio vs turn ratio calcs and design of the torid matching transformer here. Plenty of resources to help you with that.

I am considering working on a modification to my radio, but I need some guidance from the experts as I try to come up with a plan. ;-)

My goal: be able to connect the output of a QRP radio into the final stage of the TS-820 to use it as an amplifier. I assume this is possible, but please correct me if I'm wrong.

Things I think I need to look into:
- Where in the TS-820 signal paths I need to break connections and add some type of switch to choose which signal to feed into the final stage (TS-820 or external).
- Figure out what's the input power going into the final stage in the TS-820, so I try to match it (or stay below it) with the QRP radio.
Any hints on what things I need to watch out for while trying to figure out how to do this will be greatly appreciated. :-)

Thanks!

Subject: [TS-520_820_530_830] New Ham, Tuning issues

Hey guys,

I just got into amateur radio last month. I got my first HF rig at an estate sale for an old ham who passed away. I got the TS-520. The amateurs at the sale said the guy took really good care of his stuff and that this rig was recently serviced. I took it home and began to set it up.

I am operating on 40 meters with a dipole. All I have is this rig, a SWR meter, and the dipole, no other equipment for HF.

I ran through the tuning procedure in the Kenwood manual, I followed it exactly and everything went fine up to dipping the plate. The needle shows 60 ma, In order for ALC to peak, CAR needs to be set at 1.5 (anything higher and the needle pegs), and the plate reading is 80 ma, but will not dip when I turn the plate dial (which is centered on the band as per the instructions). I have also followed the tuning instructions by Ken, K4EAA and the same result happens.

I do not know for sure what my antenna's SWR is, when I attempt to use my SWR meter, it will not calibrate. I know the meter works, so I was concerned is may be an issue with the TS-520.

I have looked through the groups past posts, as well as Google, and I can't seem to find an answer to my problem. This post is the result of at least 3 days of failed research. Any help would be greatly appreciated. I can tune stations in just fine on 40 meters, but they just can't hear me (which is understandable for this situation).

Thank you guys in advance,

Jason, K7BOG

When I advance the CAR, I have to stop it at about 1.75 or when I peak it, it is outside of the ALC range. I also tried what you said, I started CAR at 0 and slowly advanced it, but the needle stopped going higher when I hit the same spot (1.75). I tried to peak it there, but the needle doesn't peak past about 80 ma.

OK then you clearly have RF output to dummy load. That means have RF drive. Now question is why no ALC indication. Sounds more like low RF drive on all bands and not no RF drive.

So trying a new 12BY7A is an easy first step.

Also, check on the VTVM at folks house and can make or buy an RF probe. Just need to measure the RF drive voltage at control grids of the finals in CW mode with the max rf output you can get. As I said assuming normal operating bias voltage you must have greater than approx 39rms rf drive volts to have any ALC indication.

If replacing Driver tube restores ALC indication in Tune mode and full RF output power we can go back to this business of Car Level pot having to be at a very low level.

This is where you need a good DMM to measure the bias voltage at the balanced modulator to see what is appearing there as you rotate the pot. Perhaps the voltage divider resistance has changed and instead of having approx 0.10vdc a low end of the pot you have a volt or so. In that case you would have instant hard turn of the ring diodes.

If you have a DMM and want to measure the Car Level voltages can do that now. Connect your DMM at BM terminal on the Gen board. Be very careful as you will be very close to HV filter caps and 900vdc. Dont let clip leads pop off BM terminal or let your hand contact the HV. You wont have to worry about getting a new driver tube.

The Balanced Mod diodes are 1N60 assuming they are the original germaniums. They have a turn on around 0.25vdc to 0.30vdc. Will start to conduct below this level.

Here are voltage levels I have recorded for the Car Level Pot steps.
1 = 0.10vdc
2 = 0.26vdc
3 = 0.30vdc
4 = 0.34vdc
5 = 0.38vdc
6 = 0.40vdc
7 = 0.42vdc
8 = 0.45vdc
9 = 0.48vdc
10 = 0.48vdc

Now you know every thing that I do.

When you say you are getting 10 watts output in SSB mode are you saying when you key the mic in SSB with mic gain turned all the way down you are getting out 10 watts? OR

I am getting 10W peaks. No carrier present. I think I remember aligning the radio when I first got it. It is pretty much working ok, but with low power.

Are you saying while modulating the rig in SSB mode (speaking into the microphone with the mic gain turned up to approx 1200) that you only see about 10 watts on voice peaks?

Yes.

These are two very different things. 10 watts on voice peaks is a little low but it depends on your mic, the mic gain setting, how you are talking in to it and a little with the ballistic characteristics of your wattmeter.

If it is the former then the Balanced Modulator carrier null/balance is probably out of adjustment assuming no problem with the ring diodes. You will need to adjust TC-1 and VR-2 on the Generator board to null and balance the carrier between LSB and USB. Will need RF probe and VTVM/DMM or O-scope to do this. We can help you perform this step. Another way to do it is with a separate receiver sitting near the 520 but not as sensitive, but probably OK at this po! int to get it close.

Yes, it is balanced. See above.

If it is the later then with rig loaded to 100 watts output it is normal to see peaks of no more than 25 to 30 watts maximum on an average reading wattmeter as you modulate the rig. If you had ALC indication would tell you to adjust mic gain to keep ALC indication within middle of the black rectangular box. Your manual will tell you to keep the peaks within the upper limit of the range. This is to prevent splatter to adjacent frequencies.

Yes, got it. Just like most other SSB rigs.

With the rig in LSB or USB you should be able to key the mic or flip to send and have no RF output power until you speak in the Mic. The Car Level pot has nothing to do with this. It can be set anywhere and have no effect on SSB power output.

Yes, no power unless modulation is present.

When you say your audio is distorted are you saying your transmit audio or receive audio? If transmit then I would perform the carrier null/balance as a first step.

When I increase the mic gain, but this could be the said splatter. I am not going to worry about this until I can get the rig to put out more power and a proper ALC reading.

Yes you can use a DMM but it is not as good for peaking and nulling as an analog meter is. It will work if that is what you have. Also, depending on your DMM it may not be 10meg input and not good for much more than measuring things like dc power supply voltages and some of the tube dc voltages. Not good for getting on grids of tubes and AGC/ALC bus work. A cheap Harbor Freight has an input Z of under 1 meg and some of the Lowes/Sears/Home Depot are around 2meg. They are for electricians and not electronic work.

Got it. For peaking. I had one when I was a teenager. I think I saw it at my parents house. I have not messed with it since the 80's.

Terry K9TW

Thanks,
Chris Maness

1.

--- In ts-520_820_530_830@yahoogroups.com, <chris@...> wrote:

Two more questions. Why would it only put out power in CW when the CAR is fully CCW (0 position)? If I increase it at all I loose all power to the antenna. At full CCW I get 10W out. This seems strange to me. However, under NO conditions do I get an ALC deflection (in TUN or CW). I have not messed with the ALC in SSB. However, I only get about 10W out in SSB too. Audio is also a bit on the crappy side. I suppose loss in linearity of the driver tube could explain the bad audio.

Can I use my modern DVM in place of a VTVM? I might have an oldy at my parent's house if they have not tossed it.

Thanks,
Chris

Chris:

I tried to respond but have not seen it yet so not sure what happened. I dont like this new format. Hard to teach old dog new tricks/.

So let me restate to make sure I fully understand.

You are telling me that you had the SG switch off, the Heaters on, in CW mode, Meter in ALC, the CAR level pot full CW or at minimum no less than at 1200 or No 5 position. When you flip to s! end and peak the Drive control thru its complete range that you get no ALC indication on any band. If that is true then most likely problem is:

Yes, you have understood me correctly I did the test 100% per your instruction. I also did the test as if I was following the tuning procedure to peak the driver as per the manual. I did this in TUN mode. Every single band showed no deflection when the CAR was at 5 and also at 10 (fully CW). I will try to get a hold of a 12BY7A and report back.

Thank you for the flow chart below.

1. Bad 12BY7A driver tube or bad dc voltages to it or bad solder connections at tube socket.

2. Bad/dirty contacts on Aux relay that switches the ALC bus voltage
3. A bad meter position switch contacts (not very common).

I would start by replacing the 12BY7A driver tube. Make sure rig is unplugged and let it set awhile to ensure voltage discharged off HV caps. Remove rig top cover to access tube on the RF board. Sometimes the ground strap can be galled and bonded to the metal shield. There is a full length split on the shield. Use a thin flat blade screw driver to spread the split. Carefully work the shield can off so you do not break the ground strap that is sandwiched between the glass envelope and metal can. When replacing the shield make sure the ground strap is placed back between the shield and the tube.

Here is where you need an RF Probe and VTVM. In 10 minutes you could measure the RF drive voltage at the control grids of the 6146 finals to see if you have RF drive greater than approx 39rms volts. Should be close to 46rms volts for full scale ALC deflection. If you are experienced with O-scope could use it as well. RF probe and VTVM are a must have if to service own Hybrid.

If new Driver tube doesnt help then try cleaning the Aux relay. Come back for the procedure for that.

In case you are interested for the above test to work you need the following:
1. Good 6146 final tubes. By good I mean good filament so there is cathode emission.
2. Good negative dc operating bias on the control grids of the finals. By good I mean voltage on control grids must switch from approx -100vdc cut off bias to approx -55vdc operating bias when you flip to Send. This is occurring as you stated you are able to set resting plate current to 60ma.

3. Good RF drive voltage at the control grids of the 6146 finals. By good I mean approx 46rms rf volts. 46 x 1.414 = 65 peak rf volts. +65 and -55 = approx +10 volts on positive peak of the drive envelope. This causes control grid to be positive with respect to the cathode and ! approx 40ua of grid current.

When the control grid of the 6146 final tubes becomes positive with respect to the cathode grid current will flow. When grid current flows the ALC amp transistor senses it and reduces the ALC bus voltage and reduces the RF drive. When the ALC bus voltage is reduced from its nominal 3.2vdc RF-1 level the ALC meter circuit sees this and drives the meter up scale. So with any hint of grid current the ALC meter should move up scale. At approx 40ua of grid current meter should be full scale.

If the Driver tube is soft could have insufficient RF voltage swing at 6146 control grids to overcome the -55vdc bias offset. For example if Driver tube is only capable of 39rms volts then 39 x 1.414 = 55 peak volts. So if RF drive is swinging the control grid to +55 volts on positive going peak of the drive envelope then +55 and -55 means Zero difference voltage and the control grid is not positive with respect to the cathode and there will be no grid current and no ALC indication.

Terry K9TW

The ALC range has nothing to do with peaking the RF Drive control. None of the meter scales are involved in this step. You just need to advance Car level pot to give yourself a good amount of indication to clearly see the peak. If the meter should peg simply reduce the Car Level pot to get the meter pointer back off the peg.

You are tuning the Driver stage tank circuit to resonance. You are not setting grid current level. I would not peak it much less than half of the ALC box as can get unstable there and be touchy to tune. 1/2 to 2/3 of the panel meter full scale is just fine level for you to be able to adjust the Drive control for a definitive peak.

What you are really looking at is the ALC bus voltage. When the Driver stage tank is properly tuned for maximum RF drive voltage swing at the 6146 control grids the ALC bus voltage will be at its lowest point. At its lowest point the ALC meter circuit drives the meter up scale.

There are Extra class KW hybrid owners who teach a caution about staying inside the ALC box when peaking the Drive control. It is sad and no amount of logic will ever convince them otherwise.

Subject: [TS-520_820_530_830] New Ham, Tuning issues

Hey guys,

I just got into amateur radio last month. I got my first HF rig at an estate sale for an old ham who passed away. I got the TS-520. The amateurs at the sale said the guy took really good care of his stuff and that this rig was recently serviced. I took it home and began to set it up.

I am operating on 40 meters with a dipole. All I have is this rig, a SWR meter, and the dipole, no other equipment for HF.

I ran through the tuning procedure in the Kenwood manual, I followed it exactly and everything went fine up to dipping the plate. The needle shows 60 ma, In order for ALC to peak, CAR needs to be set at 1.5 (anything higher and the needle pegs), and the plate reading is 80 ma, but will not dip when I turn the plate dial (which is centered on the band as per the instructions). I have also followed the tuning instructions by Ken, K4EAA and the same result happens.

I do not know for sure what my antenna's SWR is, when I attempt to use my SWR meter, it will not calibrate. I know the meter works, so I was concerned is may be an issue with the TS-520.

I have looked through the groups past posts, as well as Google, and I can't seem to find an answer to my problem. This post is the result of at least 3 days of failed research. Any help would be greatly appreciated. I can tune stations in just fine on 40 meters, but they just can't hear me (which is understandable for this situation).

Thank you guys in advance,

Jason, K7BOG

Hi Jason:

I just realized that you live nearby. I live in Meridian. Most of the folks that post on this board are FAR more technically proficient than I am but I am very comfortable tuning up and operating a Kenwood hybrid. Perhaps having a set of eyes physically present while you are going through the steps might catch something that we are missing in email.

If you'd like I could arrange to drop by and take a look. I may end up as puzzled as you but it couldn't hurt to have another set of eyes on it.

Let me know if you are interested.

73,
  Brian (K7TKT)
  Meridian, ID

I tried what you said, but the needle pegs above about 1.75 on the CAR dial. The needle won't peak above 80 ma.

Subject: [TS-520_820_530_830] New Ham, Tuning issues

Hey guys,

I just got into amateur radio last month. I got my first HF rig at an estate sale for an old ham who passed away. I got the TS-520. The amateurs at the sale said the guy took really good care of his stuff and that this rig was recently serviced. I took it home and began to set it up.

I am operating on 40 meters with a dipole. All I have is this rig, a SWR meter, and the dipole, no other equipment for HF.

I ran through the tuning procedure in the Kenwood manual, I followed it exactly and everything went fine up to dipping the plate. The needle shows 60 ma, In order for ALC to peak, CAR needs to be set at 1.5 (anything higher and the needle pegs), and the plate reading is 80 ma, but will not dip when I turn the plate dial (which is centered on the band as per the instructions). I have also followed the tuning instructions by Ken, K4EAA and the same result happens.

I do not know for sure what my antenna's SWR is, when I attempt to use my SWR meter, it will not calibrate. I know the meter works, so I was concerned is may be an issue with the TS-520.

Jason:

The best advice you got was from Bill to get a dummy load. You say you followed the TS520 instructions exactly. It does not sound like that to me.

1. Preset all the controls as listed on Page 21 Table 2. Add one control. Set the Load control to full CCW (plates fully meshed). I know you cant see them. Someday take off cover of PA cage and study whats going on here.
2. Set the Plate Idling Current to 60ma. Do that with meter in Ip, mode switch LSB/USB, mic gain turned down. Unkey the rig.
3. Set meter switch back to ALC. Set Car Level Pot to 1200. Mode switch Tune. Flip to Send and adjust the Drive control for a peak. Around 1/2 or 2/3 of full scale is a good spot to be able to see the peak. If the meter pegs then just back down the car pot and re-peak the Drive control. Now you have set the the RF drive voltage to the 6146 control grids to maximum and ready to move on to the initial plate current dip.
4. Place meter in Ip position. Flip to Send and adjust Tune control for a minimum or dip in plate current. You will not see much plate current perhaps 50ma to 60ma. Dip may not be very pronounced. On a wattmeter would see approx 10 to 15 watts peak. Return to Rec or Stand-by (unkey the rig). You are adjusting the pi-network (tank circuit) to resonance at this step with the Screen Grid voltage reduced to about 1/2 normal. This allows you to get the final tubes ready for full SG voltage and no concern about the plate current being pegged high when you first key the rig in CW mode should it be off resonance. Later you may choose to load in CW mode from the outset, but not a good idea at this time of your understanding and experience.
5. If you do not have an external wattmeter then place the panel meter in the RF position. In this position none of the meter scales are used. You are looking at a sample of RF voltage being applied to your dummy load. This is relative power and not watts. Just looking for a maximum level on the meter.
6. Flip to Send and note the meter indication. Dont leave rig keyed for more than 5 to 10 seconds. If it is very low or very high adjust the RF sensitivity pot on left side of rig to get meter indicator at approx 1/2 to 2/3 scale. Unkey the rig.
7. For the next steps do not leave rig keyed more than approx 5 to 10 seconds at a time. You are going to be opening the plates of the Load capacitor a little at a time by turning the control clockwise and adjusting the Tune capacitor for maximum RF relative power indication. As you open the plates (turn Load control CW) you are coupling load and beginning to transfer tank circuit circulating current thru the dummy load resistor instead of shunting it thru the Load capacitor.
8. Turn the Load capacitor control a few degrees clockwise (open the plates) . Flip to Send and adjust the Tune capacitor for maximum RF relative power indication. Unkey the rig. If meter pegs at any time adjust the RF sensitivity pot to bring meter indication back around 2/3 scale.
9. Turn the Load capacitor control a few more degrees clockwise. Flip to Send and adjust Tune capacitor for maximum RF indication again. Unkey the rig.
10. Repeat this two step process until you cannot get anymore RF relative power indication. Make sure you note where the peak is at each time. You can read it off the black plate

current scale. If you have opened the plates of the Load capacitor too much (too far clockwise) the RF relative power indication will start to fall off.
11. Place meter back to Ip.
12. Flip to Send and note IP reading. It should be approx 200ma. If it is you are done and ready for CW and SSB transmission.
13. If it is much above 200 ma say 225 ma to 250 ma (not likely it will be) then turn the Load control very slightly back CCW (close the plates a little) . Place meter back to RF position . Flip to Send and adjust the Tune control for maximum RF indication. Unkey the rig and place meter back to Ip.
14, Flip to Send and check IP again. Should now be closer to 200 ma and you are done. Unkey the rig. Read the section on CW and SSB transmission.

When you get better and more comfortable with this procedure you will simply at Step 8 alternately adjust the Load and Tune capacitors for maximum RF relative power indication or maximum RF output power on your external wattmeter (approx 100 watts with exception of 10 meters) at one step as you can do it quickly. Then you will check Ip to make sure not exceeding approx 200ma. It wont be a stepped procedure just a smooth one step loading.

An external wattmeter makes it nice because you can leave the panel meter in IP and just tune for approx 100 watts output and see at the same time if exceeding 200ma. It is much easier to see RF output peaks rather than plate current dip in a Class AB-1 transmitter. Also wattmeter is likely to have different ballistic characteristics than your panel meter making it easier to see changes. Also, if you see unusually high or low wattage you know there is a problem. Using the RF relative power meter and IP meter you have no idea if there is a problem. It would take the average ham a little time using just these two meters to realize that the PL-259 was not connected. With a wattmeter you know it instantly. Just makes loading a breeze for new folks.

Print this and pull it out when you get your dummy load. Remember SWR has nothing to do with your Car Level Pot.

Also if you have any reasonable level of RF output power from your rig you should be able to adjust the sensitivity pot on your SWR bridge to full scale in Forward position and then flip to Reflected and read the SWR. It doesnt care how you have loaded the rig. It just needs enough rf to get full scale deflection in Forward position and typically that is not much power. If you had RF output from your rig then it sounds like your SWR bridge is defective and not a rig problem or you have an open down stream of the SWR bridge and and will see very high reflected.

Sorry so long but essentially restating the TS520 manual.

Thanks a lot for the ton of information posted Terry! I have a lot to learn and look into, but you have definitely provided a lot to digest. I'll reply to this once I have more time to look more into the details and even try to make some of the measurements you mention (may need to ask where to tap for some of them, but I'll give it a shot first).

Thanks again for taking the time Terry! It sounds like my idea may be doable, but with a bit a work involved. I hope I have enough knowledge to figure some of these things out. ;-)

Quick question. Do you know if I would have to "tune" the radio first for the corresponding band to obtain the right plate current, load, etc, before driving the external signal into the final stage?

--- In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Cesar:

Class AB-1 doesnt really take RF drive power. Since there is no grid current can be no power consumed. Only RF voltage swing is required. However, there are rf losses from charge and discharge of the inter-electrode capacitance of the 6146 tubes at an rf rate and from cathode/heater lead inductance path. So in practice the 12BY7A driver tube does supply approx 2.0 to 2.5 watts output power to the 6146 control grid circuit.

You can estimate the output power by calculating the plate current and the dc input power and then assuming an efficiency factor for a Class A rf amplifier. To do this look at your schematic and total up the resistance in the cathode lead to ground or just measure it. Then use the cathode voltage in Tx mode listed on the schematic or measure it and use I = E/R. Some schematics show 0 cathode volts in Tx which is of course wrong.

For example for a TS830 the cathode resistance is 168 ohms and cathode voltage is 4.6vdc. Plate current (ignoring small amount of screen grid current) I = 4.6/168 = 27ma. Plate voltage = 297vdc so Dc input power is P= 297 x .027 = 8 watts. Assume Class A amplifier efficiency = 25% then 8 x .25 = 2.0 watts. If efficiency was 30% then output power = 8 x .30 = 2.4 watts.

So approx Dc input power of the KW hybrid 12BY7A Driver tube is 8 watts and approx RF output power is 2.0 to 2.5 watts.

What the control grid of the 6146 looks like to the Driver plate circuit is a complex Z. It is really Admittance that can be looked at as a capacitor and resistor in parallel and shunted from grid to cathode. It is not easy to calculate and it varies. With no grid current the Z is essentially infinite and with grid current it can be around 1000 ohms or so.

I have played around with lifting the DRV lead off the 6146 control grids and placing a carbon resistor dummy load to chassis ground and measuring the RF voltage across it. From around 1000 to 2000 ohms can get close to the same level of RF voltage as with DRV terminated on the 6146 grids. Using a 1000 ohm carbon resistor to simulate what the Driver

tube tank circuit sees isnt exactly correct and in fact may de-tune the Q of the tank.

For high power Class AB1 linear amps it is common to place a 100 ohm or so high wattage swamping resistor from grid to cathode to provide a constant impedance for the driver stage to look at so wont have distortion. We dont do that with our hybrids. We rely on a parallel resonant tank circuit at output of the Driver tube to smooth out the impedance variations under SSB modulation and very small amounts of grid current to ensure we will not have a lot of distortion and IMD generation.

You can approximate the impedance of the 6146 control grids by this formula:
Rg = (Eg max) squared/ 2 x Pd. Where Rg is the grid impedance, Eg is the peak RF drive voltage, and Pd is the peak drive power.

Here is calc for TS-830 using 47rms volts of rf grid drive at 6146 control grids (measured at 100 watts output power) 47 x 1.414 = 66 peak rf volts:

Rg = (66)squared /2 x 2 = 4356/4 = 1089 ohms

So 6146 control grids look approx like a 1100 ohm resistor with 47volts drive and -60vdc operating bias. This means if you terminate the 12BY7A DRV lead with approx 1100 ohms to ground the tube will deliver approx 2 watts.

I call these back of envelope calcs.

I suspect your QRP rig would like to look at 50 ohms so you would most likely need a broad band transformer at the control grids to get the match from 1100 ohms to approx 50 ohms? Could wind a toroid transformer or buy transformer from Mini-circuits. I wont go into the impedance ratio vs turn ratio calcs and design of the torid matching transformer here. Plenty of resources to help you with that.

You could do that to get the pi-network adjusted to resonance and antenna load, but no real need. You dont have to do that. You could make a chart of bands/frequency for the Plate Load and Plate Tune caps and pre-set them as many high power linear amp owners do.

Think of how you would load a high power linear amplifier with your KW hybrid as the exciter. No way to load the Linear without excitation so they just pre-set the Linear pi-network caps. You load the Hybrid (now serving as an exciter) into dummy load and then you drive the Linear with it . Depending on how much drive the Linear takes there are various ways to provide that level from your hybrid.

With your idea you are just replacing the Hybrid Driver stage with your QRP rig and using the finals as a Linear amp. So you would load your QRP "exciter" into a 50 ohm dummy load to 2 watts output. Then switch its output to a jack on back of Hybrid that feeds DRV on the Final board.

One thing is not likely that your QRP exciter is going to have an ALC input so will lose that control voltage. So will have to watch Ip meter or external wattmeter to adjust mic gain for proper modulation if plannng SSB operation. If CW mode only then no concern.

Also does your QRP "exciter" have a provision to key a Linear? If not then you would have to do manual switching or build a relay scheme.

Instead of using your KW hybrid PA as a Linear amp for your QRP rig. You might want to consider building a 1 or 2 tube 6146 linear amp. Would be a great learning project to scrounge the parts for it and its power supply. Also great sense of accomplishment. Maybe buy a tech special TS520 and pull the parts from it.
.

Take a look at this simple design. Older QST issues also have similar designs.

I also forgot to mention you could buy a Heathkit DX-20, DX-35, DX-40 and use your QRP rig to replace the Driver stage in it. This would be a simple and low cost approach.

Probably the cheapest thing you can do as buying parts today is not what it use to be as far as availability and cost. We use to search for and buy most of our parts by hamfesting which was part of the fun and eBay kind of took care of that for us.

Class AB-1 doesnt really take RF drive power. Since there is no grid current can be no power consumed. Only RF voltage swing is required. However, there are rf losses from charge and discharge of the inter-electrode capacitance of the 6146 tubes at an rf rate and from cathode/heater lead inductance path. So in practice the 12BY7A driver tube does supply approx 2.0 to 2.5 watts output power to the 6146 control grid circuit.

You can estimate the output power by calculating the plate current and the dc input power and then assuming an efficiency factor for a Class A rf amplifier. To do this look at your schematic and total up the resistance in the cathode lead to ground or just measure it. Then use the cathode voltage in Tx mode listed on the schematic or measure it and use I = E/R. Some schematics show 0 cathode volts in Tx which is of course wrong.

For example for a TS830 the cathode resistance is 168 ohms and cathode voltage is 4.6vdc. Plate current (ignoring small amount of screen grid current) I = 4.6/168 = 27ma. Plate voltage = 297vdc so Dc input power is P= 297 x .027 = 8 watts. Assume Class A amplifier efficiency = 25% then 8 x .25 = 2.0 watts. If efficiency was 30% then output power = 8 x .30 = 2.4 watts.

So approx Dc input power of the KW hybrid 12BY7A Driver tube is 8 watts and approx RF output power is 2.0 to 2.5 watts.

What the control grid of the 6146 looks like to the Driver plate circuit is a complex Z. It is really Admittance that can be looked at as a capacitor and resistor in parallel and shunted from grid to cathode. It is not easy to calculate and it varies. With no grid current the Z is essentially infinite and with grid current it can be around 1000 ohms or so.

I have played around with lifting the DRV lead off the 6146 control grids and placing a carbon resistor dummy load to chassis ground and measuring the RF voltage across it. From around 1000 to 2000 ohms can get close to the same level of RF voltage as with DRV terminated on the 6146 grids. Using a 1000 ohm carbon resistor to simulate what the Driver tube tank circuit sees isnt exactly correct and in fact may de-tune the Q of the tank.

For high power Class AB1 linear amps it is common to place a 100 ohm or so high wattage swamping resistor from grid to cathode to provide a constant impedance for the driver stage to look at so wont have distortion. We dont do that with our hybrids. We rely on a parallel resonant tank circuit at output of the Driver tube to smooth out the impedance variations under SSB modulation and very small amounts of grid current to ensure we will not have a

lot of distortion and IMD generation.

You can approximate the impedance of the 6146 control grids by this formula:
Rg = (Eg max) squared/ 2 x Pd. Where Rg is the grid impedance, Eg is the peak RF drive voltage, and Pd is the peak drive power.

Here is calc for TS-830 using 47rms volts of rf grid drive at 6146 control grids (measured at 100 watts output power) 47 x 1.414 = 66 peak rf volts:

Rg = (66)squared /2 x 2 = 4356/4 = 1089 ohms

So 6146 control grids look approx like a 1100 ohm resistor with 47volts drive and -60vdc operating bias. This means if you terminate the 12BY7A DRV lead with approx 1100 ohms to ground the tube will deliver approx 2 watts.

I call these back of envelope calcs.

I suspect your QRP rig would like to look at 50 ohms so you would most likely need a broad band transformer at the control grids to get the match from 1100 ohms to approx 50 ohms? Could wind a toroid transformer or buy transformer from Mini-circuits. I wont go into the impedance ratio vs turn ratio calcs and design of the torid matching transformer here. Plenty of resources to help you with that.

Cesar:

I am sorry for so much detail. My interest in understanding how these hybrids works often gets in the way of a succinct answer.

I saw your call letters and the question about Driver stage power led me to believe you were perhaps more experienced.

Of course nothing wrong with your question as Hams have been experimenting and modifying and converting for years.

Maybe just print the response and file it away. If you do pursue this and make your own measurements I would be interested in your results.

A simple answer would have been something like approx 2.0 to 2.5 watts output and input Z varies and will likely need to use a matching transformer between the QRP rig and 6146 control grids.

I get carried away and like to discuss this kind of thing with folks with common interest. A little hard to find those folks today.

If you decide to pursue email me off the forum and we can discuss and not use the bandwidth here.

Thanks a lot for the ton of information posted Terry! I have a lot to learn and look into, but you have definitely provided a lot to digest. I'll reply to this once I have more time to look more into the details and even try to make some of the measurements you mention (may need to ask where to tap for some of them, but I'll give it a shot first).

Thanks again for taking the time Terry! It sounds like my idea may be doable, but with a bit a work involved. I hope I have enough knowledge to figure some of these things out. ;-)

Quick question. Do you know if I would have to "tune" the radio first for the corresponding band to obtain the right plate current, load, etc, before driving the external signal into the final stage?

Topic: 44489 Message: 44489

Hi folks. New to group so be gentle !!
My newly acquired TS-830S seems in v good condition. RX is great compared with a couple of "modern" rigs and great SSB audio reports. 100w+ out on all bands, CW key down, with Car level at 12 o'clock.
My problem is that when using the MC-50 mic I am finding that to get the ALC to move to around half scale, all bands, I need to talk with the mic very close, ie a couple of inches, even with mic gain at max. (Proc off). Vox operation seems fine, so I assume audio 1st stage amp gain is ok. Is this normal with this mic ??
I would really like to use mic at a more comfortable distance, ie 6 - 8 inches, without using Processor. Is it worthwhile trying my Behringer 502 mic amp/mixer in line with mic ?
I do understand that this amp is really designed for low imp mics, and it's use will no doubt mess up the great "Kenwood audio" reports I am currently getting.
Any advice on this, other than changing the mic ?
Regards
Dave

Hi, Terry:

I have the resistors on order for the dummy load, I should have it built on Saturday.

I followed the manual exactly, but I did follow your posted instructions, and the same result happened.

1. All switches and dials were preset to the table in the manual.
2. I confirmed again, the current is set at 60 ma,
3. For setting CAR, I started with the dial at 12:00, the needle pegs, so I turned it down. The needle peaks at the highest mark on the ALC meter line when my CAR is set to about 1.75
4. This step is where I always have my problem. The needle starts out at the 85 ma position and doesn't move at all when I turn the Plate dial. I have to stop tuning at this step because I can't get the needle to move at all.

I can see how a wattmeter would be nice to have, but I don't own one. I am on a bit of a tight budget right now, and I can't really afford it right now.

I will try all of this again when I get my dummy load built on Saturday, but where I stand now is the problem I keep on having.

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Jason:

The best advice you got was from Bill to get a dummy load. You say you followed the TS520 instructions exactly. It does not sound like that to me.

1. Preset all the controls as listed on Page 21 Table 2. Add one control. Set the Load control to full CCW (plates fully meshed). I know you cant see them. Someday take off cover of PA cage and study whats going on here.
2. Set the Plate Idling Current to 60ma. Do that with meter in Ip, mode switch LSB/USB, mic gain turned down. Unkey the rig.
3. Set meter switch back to ALC. Set Car Level Pot to 1200. Mode switch Tune. Flip to Send and adjust the Drive control for a peak. Around 1/2 or 2/3 of full scale is a good spot to be able to see the peak. If the meter pegs then just back down the car pot and re-peak the Drive control. Now you have set the the RF drive voltage to the 6146 control grids to maximum and ready to move on to the initial plate current dip.
4. Place meter in Ip position. Flip to Send and adjust Tune control for a minimum or dip in plate current. You will not see much plate current perhaps 50ma to 60ma. Dip may not be very pronounced. On a wattmeter would see approx 10 to 15 watts peak. Return to Rec or Stand-by (unkey the rig). You are adjusting the pi-network (tank circuit) to resonance at this step with the Screen Grid voltage reduced to about 1/2 normal. This allows you to get the final tubes ready for full SG voltage and no concern about the plate current being pegged high when you first key the rig in CW mode should it be off resonance. Later you may choose to load in CW mode from the outset, but not a good idea at this time of your understanding and experience.

5. If you do not have an external wattmeter then place the panel meter in the RF position. In this position none of the meter scales are used. You are looking at a sample of RF voltage being applied to your dummy load. This is relative power and not watts. Just looking for a maximum level on the meter.
6. Flip to Send and note the meter indication. Dont leave rig keyed for more than 5 to 10 seconds. If it is very low or very high adjust the RF sensitivity pot on left side of rig to get meter indicator at approx 1/2 to 2/3 scale. Unkey the rig.
7. For the next steps do not leave rig keyed more than approx 5 to 10 seconds at a time. You are going to be opening the plates of the Load capacitor a little at a time by turning the control clockwise and adjusting the Tune capacitor for maximum RF relative power indication. As you open the plates (turn Load control CW) you are coupling load and beginning to transfer tank circuit circulating current thru the dummy load resistor instead of shunting it thru the Load capacitor.
8. Turn the Load capacitor control a few degrees clockwise (open the plates) . Flip to Send and adjust the Tune capacitor for maximum RF relative power indication. Unkey the rig. If meter pegs at any time adjust the RF sensitivity pot to bring meter indication back around 2/3 scale.
9. Turn the Load capacitor control a few more degrees clockwise. Flip to Send and adjust Tune capacitor for maximum RF indication again. Unkey the rig.
10. Repeat this two step process until you cannot get anymore RF relative power indication. Make sure you note where the peak is at each time. You can read it off the black plate current scale. If you have opened the plates of the Load capacitor too much (too far clockwise) the RF relative power indication will start to fall off.
11. Place meter back to Ip.
12. Flip to Send and note IP reading. It should be approx 200ma. If it is you are done and ready for CW and SSB transmission.
13. If it is much above 200 ma say 225 ma to 250 ma (not likely it will be) then turn the Load control very slightly back CCW (close the plates a little) . Place meter back to RF position . Flip to Send and adjust the Tune control for maximum RF indication. Unkey the rig and place meter back to Ip.
14, Flip to Send and check IP again. Should now be closer to 200 ma and you are done. Unkey the rig. Read the section on CW and SSB transmission.

When you get better and more comfortable with this procedure you will simply at Step 8 alternately adjust the Load and Tune capacitors for maximum RF relative power indication or maximum RF output power on your external wattmeter (approx 100 watts with exception of 10 meters) at one step as you can do it quickly. Then you will check Ip to make sure not exceeding approx 200ma. It wont be a stepped procedure just a smooth one step loading.

An external wattmeter makes it nice because you can leave the panel meter in IP and just tune for approx 100 watts output and see at the same time if exceeding 200ma. It is much easier to see RF output peaks rather than plate current dip in a Class AB-1 transmitter. Also wattmeter is likely to have different ballistic characteristics than your panel meter making it easier to see changes. Also, if you see unusually high or low wattage you know there is a problem. Using the RF relative power meter and IP meter you have no idea if there is a problem. It would take the average ham a little time using just these two meters to realize that the PL-259 was not connected. With a wattmeter you know it instantly. Just makes loading a breeze for new folks.

Print this and pull it out when you get your dummy load. Remember SWR has nothing to do with your Car Level Pot.

Also if you have any reasonable level of RF output power from your rig you should be able to adjust the sensitivity pot on your SWR bridge to full scale in Forward position and then flip to Reflected and read the SWR. It doesnt care how you have loaded the rig. It just needs enough rf to get full scale deflection in Forward position and typically that is not much power. If you had RF output from your rig then it sounds like your SWR bridge is defective and not a rig problem or you have an open down stream of the SWR bridge and and will see very high reflected.

Sorry so long but essentially restating the TS520 manual.

Terry K9TW

Hey guys,

I just got into amateur radio last month. I got my first HF rig at an estate sale for an old ham who passed away. I got the TS-520. The amateurs at the sale said the guy took really good care of his stuff and that this rig was recently serviced. I took it home and began to set it up.

I am operating on 40 meters with a dipole. All I have is this rig, a SWR meter, and the dipole, no other equipment for HF.

I ran through the tuning procedure in the Kenwood manual, I followed it exactly and everything went fine up to dipping the plate. The needle shows 60 ma, In order for ALC to peak, CAR needs to be set at 1.5 (anything higher and the needle pegs), and the plate reading is 80 ma, but will not dip when I turn the plate dial (which is centered on the band as per the instructions). I have also followed the tuning instructions by Ken, K4EAA and the same result happens.

I do not know for sure what my antenna's SWR is, when I attempt to use my SWR meter, it will not calibrate. I know the meter works, so I was concerned is may be an issue with the TS-520.

I have looked through the groups past posts, as well as Google, and I can't seem to find an answer to my problem. This post is the result of at least 3 days of failed research. Any help would be greatly appreciated. I can tune stations in just fine on 40 meters, but they just can't hear me (which is understandable for this situation).

Thank you guys in advance,

Jason, K7BOG

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

I tried what you said, but the needle pegs above about 1.75 on the CAR dial. The needle won't peak above 80 ma.

Subject: [TS-520_820_530_830] New Ham, Tuning issues

Hey guys,

I just got into amateur radio last month. I got my first HF rig at an estate sale for an old ham who passed away. I got the TS-520. The amateurs at the sale said the guy took really good care of his stuff and that this rig was recently serviced. I took it home and

began to set it up.

I am operating on 40 meters with a dipole. All I have is this rig, a SWR meter, and the dipole, no other equipment for HF.

I ran through the tuning procedure in the Kenwood manual, I followed it exactly and everything went fine up to dipping the plate. The needle shows 60 ma, In order for ALC to peak, CAR needs to be set at 1.5 (anything higher and the needle pegs), and the plate reading is 80 ma, but will not dip when I turn the plate dial (which is centered on the band as per the instructions). I have also followed the tuning instructions by Ken, K4EAA and the same result happens.

I do not know for sure what my antenna's SWR is, when I attempt to use my SWR meter, it will not calibrate. I know the meter works, so I was concerned is may be an issue with the TS-520.

I have looked through the groups past posts, as well as Google, and I can't seem to find an answer to my problem. This post is the result of at least 3 days of failed research. Any help would be greatly appreciated. I can tune stations in just fine on 40 meters, but they just can't hear me (which is understandable for this situation).

Thank you guys in advance,

Jason, K7BOG

Make sure the MC-50's impedance is set to HIGH to match the radio. This is done by lining up the red dot on the microphone body near the connector and with one on the connector itself.

The MC-50's manual, such as it is, is available online with an explanation of its impedance matching feature.

Hi Jan:

That is a great idea. You can experiment with the SG supply and you can meter the thing so you can see what is going on. A zero center meter for screen grid current would be good. You will have to decide if you will use the ALC. I dont know how you would be able to use the RF Negative feedback. Its a copy of Collins early SSB circuit.

When you get it done I would be interested to see what you did at the control grids to couple the Flex drive signal. All kinds of options. If you look at what Dr. Latta did he used link couplng and a LC tank circuit. Could use Pi-network, but I think I would like to explore broad band transformer?

Be curious to see how you calculate the input Z. I think one of few people I know who could do a back of envelope calc for a grid driven tetrode input is Ray. Most folks build grounded grid today and lots of info and easy to calc what the cathode looks like to the exciter. Dont see as much info for grid driven amps. You have great resource with that group.

Lots of fun.

OK there is no problem peaking the RF Drive control with Car Level Pot at 1.75 position. Peaking at the max of the ALC printed black range as I have said more than once is meaningless. If it makes you happy that is good. Just peak it where ever you want so Driver plate circuit is tuned to resonance so you have sufficient RF drive.

Now you must switch the meter from ALC to IP position. Are you doing that?

Also as I told you pre-set the LOAD capacitor to full CCW. This will allow you to see some level of plate current dip. If you have the LOAD control half open or more you wont see much dip at all. The manual does not tell you to do this.

You should still be in Tune mode and then Flip to Send. Are you saying at this point you see 85ma of Ip (plate current) and you cannot get that current to dip or increase in value when you adjust the TUNE Control?

Are you swinging the TUNE control over a large range or just barely tweaking it at its pre-set 7mhz band position on the white arc?

There is one other possibility and that is the shaft coupler set screws at the PA cage end of the shaft may be loose and when you are turning the TUNE knob it is not mechanically coupled to the TUNE capacitor shaft that protrudes from the cage and not opening and closing its plates. This is not common, but it does happen. When you turn the TUNE control knob with the rig in receive mode does it turn approx 3/4 of its travel and come to a positive stop or can you just turn it continuously?

Sometimes people remove the stop collar screw or it backs out and the white mark on the knob no longer aligns with the white band markings on the front panel.

Hi, Terry:

I have the resistors on order for the dummy load, I should have it built on Saturday.

I followed the manual exactly, but I did follow your posted instructions, and the same result happened.

1. All switches and dials were preset to the table in the manual.
2. I confirmed again, the current is set at 60 ma,
3. For setting CAR, I started with the dial at 12:00, the needle pegs, so I turned it down. The needle peaks at the highest mark on the ALC meter line when my CAR is set to about 1.75
4. This step is where I always have my problem. The needle starts out at the 85 ma position and doesn't move at all when I turn the Plate dial. I have to stop tuning at this step because I can't get the needle to move at all.

I can see how a wattmeter would be nice to have, but I don't own one. I am on a bit of a tight budget right now, and I can't really afford it right now.

I will try all of this again when I get my dummy load built on Saturday, but where I stand now is the problem I keep on having.

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Jason:

The best advice you got was from Bill to get a dummy load. You say you followed the TS520 instructions exactly. It does not sound like that to me.

1. Preset all the controls as listed on Page 21 Table 2. Add one control. Set the Load control to full CCW (plates fully meshed). I know you cant see them. Someday take off cover of PA cage and study whats going on here.
2. Set the Plate Idling Current to 60ma. Do that with meter in Ip, mode switch LSB/USB, mic gain turned down. Unkey the rig.
3. Set meter switch back to ALC. Set Car Level Pot to 1200. Mode switch Tune. Flip to Send and adjust the Drive control for a peak. Around 1/2 or 2/3 of full scale is a good spot to be able to see the peak. If the meter pegs then just back down the car pot and re-peak the Drive control. Now you have set the the RF drive voltage to the 6146 control grids to maximum and ready to move on to the initial plate current dip.
4. Place meter in Ip position. Flip to Send and adjust Tune control for a minimum or dip in plate current. You will not see much plate current perhaps 50ma to 60ma. Dip may not be very pronounced. On a wattmeter would see approx 10 to 15 watts peak. Return to Rec or Stand-by (unkey the rig). You are adjusting the pi-network (tank circuit) to resonance at this step with the Screen Grid voltage reduced to about 1/2 normal. This allows you to get the final tubes ready for full SG voltage and no concern about the plate current being pegged high when you first key the rig in CW mode should it be off resonance. Later you may choose to load in CW mode from the outset, but not a good idea at this time of your understanding and experience.
5. If you do not have an external wattmeter then place the panel meter in the RF position. In this position none of the meter scales are used. You are looking at a sample of RF voltage being applied to your dummy load. This is relative power and not watts. Just looking for a maximum level on the meter.
6. Flip to Send and note the meter indication. Dont leave rig keyed for more than 5 to 10 seconds. If it is very low or very high adjust the RF sensitivity pot on left side of rig to get meter indicator at approx 1/2 to 2/3 scale. Unkey the rig.
7. For the next steps do not leave rig keyed more than approx 5 to 10 seconds at a time. You are going to be opening the plates of the Load capacitor a little at a time by turning the control clockwise and adjusting the Tune capacitor for maximum RF relative power indication. As you open the plates (turn Load control CW) you are coupling load and beginning to transfer tank circuit circulating current thru the dummy load resistor instead of shunting it thru the Load capacitor.
8. Turn the Load capacitor control a few degrees clockwise (open the plates) . Flip to Send and adjust the Tune capacitor for maximum RF relative power indication. Unkey the rig. If meter pegs at any time adjust the RF sensitivity pot to bring meter indication back around 2/3 scale.
9. Turn the Load capacitor control a few more degrees clockwise. Flip to Send and adjust Tune capacitor for maximum RF indication again. Unkey the rig.
10. Repeat this two step process until you cannot get anymore RF relative power indication.

Make sure you note where the peak is at each time. You can read it off the black plate current scale. If you have opened the plates of the Load capacitor too much (too far clockwise) the RF relative power indication will start to fall off.
11. Place meter back to Ip.
12. Flip to Send and note IP reading. It should be approx 200ma. If it is you are done and ready for CW and SSB transmission.
13. If it is much above 200 ma say 225 ma to 250 ma (not likely it will be) then turn the Load control very slightly back CCW (close the plates a little) . Place meter back to RF position . Flip to Send and adjust the Tune control for maximum RF indication. Unkey the rig and place meter back to Ip.
14, Flip to Send and check IP again. Should now be closer to 200 ma and you are done. Unkey the rig. Read the section on CW and SSB transmission.

When you get better and more comfortable with this procedure you will simply at Step 8 alternately adjust the Load and Tune capacitors for maximum RF relative power indication or maximum RF output power on your external wattmeter (approx 100 watts with exception of 10 meters) at one step as you can do it quickly. Then you will check Ip to make sure not exceeding approx 200ma. It wont be a stepped procedure just a smooth one step loading.

An external wattmeter makes it nice because you can leave the panel meter in IP and just tune for approx 100 watts output and see at the same time if exceeding 200ma. It is much easier to see RF output peaks rather than plate current dip in a Class AB-1 transmitter. Also wattmeter is likely to have different ballistic characteristics than your panel meter making it easier to see changes. Also, if you see unusually high or low wattage you know there is a problem. Using the RF relative power meter and IP meter you have no idea if there is a problem. It would take the average ham a little time using just these two meters to realize that the PL-259 was not connected. With a wattmeter you know it instantly. Just makes loading a breeze for new folks.

Print this and pull it out when you get your dummy load. Remember SWR has nothing to do with your Car Level Pot.

Also if you have any reasonable level of RF output power from your rig you should be able to adjust the sensitivity pot on your SWR bridge to full scale in Forward position and then flip to Reflected and read the SWR. It doesnt care how you have loaded the rig. It just needs enough rf to get full scale deflection in Forward position and typically that is not much power. If you had RF output from your rig then it sounds like your SWR bridge is defective and not a rig problem or you have an open down stream of the SWR bridge and and will see very high reflected.

Sorry so long but essentially restating the TS520 manual.

Gordon has uploaded one of my videosto his server. The video isa simple ohms law circuit test for anyone to take to measure your basic ohms law knowledge. The circuit is simple, values are shown in the video, and the video includes 4 simple questions. You can access the video at the following link:

http://www.n6wk.com/w5rkl/Simple%20Ohms%20Law%20test.wmv

You can submit your answers to either the group or via private email to me, it's up to you. The video is designed primarily for those who are studying/learning aboutand how to use ohms law but it can be a refresher for those who have used ohms law in the past but would like a refresher.

I'm working with Gordon so I have can upload the videos myself. I currently have a video that shows whathappens if a single component value changes and what effects that single component's change in value has on the overall circuit. Hope to have it uploaded soon.

If the transceiver is the TS-830, which it appears it is, then the MC-50 can be set for either low or high impedance. The TS-830 has a microphone impedance range from 500 ohms to 50K ohms (see the 830's operator's specification page in the operator's manual).

Thanks for advice. Yes I have read somewhere that some folk mask some of the mic side slots, and get improvement.
Like the idea of a single transistor amp built into base. May try this over next few days.
Suppose virtually any low signal NPN will do. maybe 2N2222 would do job.
Thanks

Joe:

You have obviously made up your mind to sell off your KW Hybrid gear and test equipment. I hate to see that. I hope you did not get discouraged by perceived lack of help or the kind of help you got on this forum.

"Electronic" help is never going be as good as a local Elmer can provide you. It can certainly be a little overwhelming to learn how to use the test gear and read schematics etc.

With the test gear you have (assuming it is working) you should be able to do about 95% of what you need to do on any Hybrid. True some rigs can be real dogs. I have spent many hours trying to figure out what has been done to them. It can be discouraging trying to work with what is essentially junk.

Sometimes you need to cut bait and sell the problem rig and look for a better rig. They are out there.

Subject: [TS-520_820_530_830] TS530 and Test Equipment FOR SALE

I have had all of this since I was first licensed and have just never got around to learning how to work on the TS530 yet.

The 530 has some issues that I can give more details on. All the rest is used with fairly normal wear.

TS530S (Included spare HV Caps, resistor kit, driver tube) - $200
AT230 - $200
VFO240 - $150
MC50 - $50
SP520 - $25

LeCroy 9400 125MHz Dual Channel O-Scope (with probes) $500
Heathkit IM18 VTVM - $35

Heathkit 309C Probe - $20
HP 5382A Freq. Counter - $50
Eico 232 VTVM (bent needle) - $10

You can contact me via email KD8MAB (at) the-eatons (dot) com with other questions.
(Prices do not include shipping)

Joe

If you want more punch in your MC-50, just slide an empty toilet paper roll (or something similar) over the mike end and talk into the other end of the paper roll. Based on past technical analysis, too long of a paper roll (Reynolds foil type paper tube) and your audio will develop a severe punchy hollow sound.

Subject: Re: [TS-520_820_530_830] TS-830S and MC-50 Mic sensitivety

Dave,
The MC50 is a 'close talk' mike. A couple of inches.
Try taping-over the front half of the side slots for better articulation.
Read previous posts in mic alc topic.

If you feel that you need an external mic amp, experiment and make notes!
I built a one-transistor amp into the base of my MC50. Current draw is <100uA so the 9v battery lasts well over a year.

The circuit is the simplest.
Mic input via a 1uF cap to base of a BCxxx which is biased by 390k+.
Output from collector via 1uF cap.
Emitter grounded.
Collector 9v+ alcaline via a 10k resistor.
Veroboard construction.

Try the tape first as it's easy.
I made mp3s before and after and subtracted 'before' then compared them on Excel.
Bass and treble were slightly enhanced.

Hi
My TS 520 has a dead spot when trying to adjust the ALC level. The dead spot is where I would like to set ALC. Probably in the mic adj . I turn the mic control clockwise and the meter needle moves to the right to a point where it drops back to zero. If I continue to turn clockwise the needle will bounce back up but then is out of range. Is there a fix for this.

Topic: 44489 Message: 44511

Dave F4EYK,

You are correct, the TS-820 has a high microphone impedance of 50K.
However, the initial post/discussion/question is not about a TS-820but
rather it's about a TS-830(see the segment of the initial post cut and
pasted below) and the MC-50 microphone:

"/My newly acquired TS-830S seems in v good condition. RX is great
compared with a couple of "modern" rigs and great SSB audio reports.
100w+ out on all bands, CW key down, with Car level at 12 o'clock. My
problem is that when using the MC-50 mic I am finding that to get the
ALC to move to around half scale, all bands.../"

There is no indication/mention of a TS-820 anywhere in the initial post.

The TS-830 has a wide microphone impedance range from 500 ohms to 50K ohms.

Greg:

Are you talking about:

1. Setting the Car Level pot for a particular meter indication while adjusting the Drive control when loading the radio?

2. Speaking into the microphone in SSB mode and adjusting the mic gain pot as you speak for a particular amount of ALC indication on voice peaks?

When you adjust the mic gain there should be no ALC indication unless you are speaking into the microphone in LSB or USB mode.

Topic: 44440 Message: 44513

Hi all:

Thanks for your help with Jason's tuning issues.

I went over to his station to look at his TS-520. I took my dummy load, straight key and AT230 to give us a little better set up for our efforts.

Here is what we did:
1. Hooked up the AT230 and dummy load. Set the antenna to point to the dummy load
2. Band to 40m
3. Verified that the plate idling current is 60ma.
4. Went through the typical Kenwood hybrid tune up
4a. Verified starting switch positions
4b. Tune position, ALC meter, AT230 to power
4c. Peaked drive for about 2/3 meter
4d. IP meter
4e. Dipped the plate (To this point everything on the 520 meter and the AT230 power reading looked the same as it does when I tune up my 830---It all looked normal to me.)
4f. Mode to CW. VOX on

4g. Closed the key (Even with no load the IP is showing 200ma and the power out is about 70w.)
4h. I advanced the load a bit (CW), keyed the rig and dipped the plate again. The plate current was higher but the power out was lower. No matter where I set the load/dipped the plate, the highest output was with minimum load (fully CCW).
5. Tried the same procedure on 20m. Same results
6. Advancing the carrier to 225ma with the load at minimum, plate dipped, produces 100w.
7. After this I checked Jason's antenna...the SWR is about 10:1 (he is working on that). He also has resistors on order to use to construct his own dummy load.

8. We listened around the bands a bit. The radio seems to hear fine.

So...I think the problem where he wasn't getting a dip in the plate current before (previous email) was probably because the load was fully CW instead of fully CCW at that time. Trying to tune into a 10:1 antenna was probably not helping things.

Questions:
1. Thoughts on the load issue? Seems like the load range we want is somewhere beyond the minimum of what we are getting now. It is possible that the minimum setting happens to be just the load we want but that doesn't seem right.

Both Jason and I have fairly limited technical skills working inside the radio. I've done the basic stuff (cleaned relays, performed an alignment, etc.) but that is about the limit of my experience (so far---learning acquiring test equipment as things come up.)

Thanks,
  Brian (K7TKT)

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

Jason:

The best advice you got was from Bill to get a dummy load. You say you followed the TS520 instructions exactly. It does not sound like that to me.

1. Preset all the controls as listed on Page 21 Table 2. Add one control. Set the Load control to full CCW (plates fully meshed). I know you cant see them. Someday take off cover of PA cage and study whats going on here.
2. Set the Plate Idling Current to 60ma. Do that with meter in Ip, mode switch LSB/USB, mic gain turned down. Unkey the rig.
3. Set meter switch back to ALC. Set Car Level Pot to 1200. Mode switch Tune. Flip to Send and adjust the Drive control for a peak. Around 1/2 or 2/3 of full scale is a good spot to be able to see the peak. If the meter pegs then just back down the car pot and re-peak the Drive control. Now you have set the the RF drive voltage to the 6146 control grids to maximum and ready to move on to the initial plate current dip.
4. Place meter in Ip position. Flip to Send and adjust Tune control for a minimum or dip in plate current. You will not see much plate current perhaps 50ma to 60ma. Dip may not be very pronounced. On a wattmeter would see approx 10 to 15 watts peak. Return to Rec or Stand-by (unkey the rig). You are adjusting the pi-network (tank circuit) to resonance at this step with the Screen Grid voltage reduced to about 1/2 normal. This allows you to get the final tubes ready for full SG voltage and no concern about the plate current being pegged high when you first key the rig in CW mode should it be off resonance. Later you may choose to load in CW mode from the outset, but not a good idea at this time of your understanding and experience.
5. If you do not have an external wattmeter then place the panel meter in the RF position. In this position none of the meter scales are used. You are looking at a sample of RF voltage being applied to your dummy load. This is relative power and not watts. Just looking for a maximum level on the meter.
6. Flip to Send and note the meter indication. Dont leave rig keyed for more than 5 to 10 seconds. If it is very low or very high adjust the RF sensitivity pot on left side of rig to get meter indicator at approx 1/2 to 2/3 scale. Unkey the rig.
7. For the next steps do not leave rig keyed more than approx 5 to 10 seconds at a time. You are going to be opening the plates of the Load capacitor a little at a time by turning the control clockwise and adjusting the Tune capacitor for maximum RF relative power indication. As you open the plates (turn Load control CW) you are coupling load and beginning to transfer tank circuit circulating current thru the dummy load resistor instead of shunting it thru the Load capacitor.
8. Turn the Load capacitor control a few degrees clockwise (open the plates) . Flip to Send and adjust the Tune capacitor for maximum RF relative power indication. Unkey the rig. If meter pegs at any time adjust the RF sensitivity pot to bring meter indication back around 2/3 scale.
9. Turn the Load capacitor control a few more degrees clockwise. Flip to Send and adjust Tune capacitor for maximum RF indication again. Unkey the rig.
10. Repeat this two step process until you cannot get anymore RF relative power indication. Make sure you note where the peak is at each time. You can read it off the black plate current scale. If you have opened the plates of the Load capacitor too much (too far

clockwise) the RF relative power indication will start to fall off.
11. Place meter back to Ip.
12. Flip to Send and note IP reading. It should be approx 200ma. If it is you are done and ready for CW and SSB transmission.
13. If it is much above 200 ma say 225 ma to 250 ma (not likely it will be) then turn the Load control very slightly back CCW (close the plates a little) . Place meter back to RF position . Flip to Send and adjust the Tune control for maximum RF indication. Unkey the rig and place meter back to Ip.
14, Flip to Send and check IP again. Should now be closer to 200 ma and you are done. Unkey the rig. Read the section on CW and SSB transmission.

When you get better and more comfortable with this procedure you will simply at Step 8 alternately adjust the Load and Tune capacitors for maximum RF relative power indication or maximum RF output power on your external wattmeter (approx 100 watts with exception of 10 meters) at one step as you can do it quickly. Then you will check Ip to make sure not exceeding approx 200ma. It wont be a stepped procedure just a smooth one step loading.

An external wattmeter makes it nice because you can leave the panel meter in IP and just tune for approx 100 watts output and see at the same time if exceeding 200ma. It is much easier to see RF output peaks rather than plate current dip in a Class AB-1 transmitter. Also wattmeter is likely to have different ballistic characteristics than your panel meter making it easier to see changes. Also, if you see unusually high or low wattage you know there is a problem. Using the RF relative power meter and IP meter you have no idea if there is a problem. It would take the average ham a little time using just these two meters to realize that the PL-259 was not connected. With a wattmeter you know it instantly. Just makes loading a breeze for new folks.

Print this and pull it out when you get your dummy load. Remember SWR has nothing to do with your Car Level Pot.

Also if you have any reasonable level of RF output power from your rig you should be able to adjust the sensitivity pot on your SWR bridge to full scale in Forward position and then flip to Reflected and read the SWR. It doesnt care how you have loaded the rig. It just needs enough rf to get full scale deflection in Forward position and typically that is not much power. If you had RF output from your rig then it sounds like your SWR bridge is defective and not a rig problem or you have an open down stream of the SWR bridge and and will see very high reflected.

Sorry so long but essentially restating the TS520 manual.

Terry K9TW

Hey guys,

I just got into amateur radio last month. I got my first HF rig at an estate sale for an old ham who passed away. I got the TS-520. The amateurs at the sale said the guy took really good care of his stuff and that this rig was recently serviced. I took it home and began to set it up.

I am operating on 40 meters with a dipole. All I have is this rig, a SWR meter, and the dipole, no other equipment for HF.

I ran through the tuning procedure in the Kenwood manual, I followed it exactly and everything went fine up to dipping the plate. The needle shows 60 ma, In order for ALC to peak, CAR needs to be set at 1.5 (anything higher and the needle pegs), and the plate reading is 80 ma, but will not dip when I turn the plate dial (which is centered on the band as per the instructions). I have also followed the tuning instructions by Ken, K4EAA and the same result happens.

I do not know for sure what my antenna's SWR is, when I attempt to use my SWR meter, it will not calibrate. I know the meter works, so I was concerned is may be an issue with the TS-520.

I have looked through the groups past posts, as well as Google, and I can't seem to find an answer to my problem. This post is the result of at least 3 days of failed research. Any help would be greatly appreciated. I can tune stations in just fine on 40 meters, but they just can't hear me (which is understandable for this situation).

Thank you guys in advance,

Jason, K7BOG

Ok, I tried a couple of different driver tubes now. With on RCA that
appeared to be NOS, I doubled my output power to 20W, but no ALC deflection
in tune. With a generic tube I am getting 60W out in CW. However, still
no ALC deflection in TUN mode. No matter what the settings. The ALC meter
does deflect in USB/LSB. I would say that the meter function seems normal.
I get very little power out in SSB, and using a dummy load and my little
FT-817 for a monitor, the audio sounds pretty crappy.

Hope this helps the trouble shooting process.

44515. Replacing the Power Rectifier Board - 520SE. ONE PROBLEM!

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-14 01:51:16 UTC
From: Wes Will
Topic: 44440 Message: 44515

Ken, the board you sent me, with the exact same numbers screened on it (X43-1090-00) as the dead one

has one less pin and a totally different layout than the dead original.

The original board had a pin labeled

STB

And the new board does NOT. The old board with the STB connection (white-purple stripe wire) was to the junction of two resistors, R9 and R10. The other end of R9 went to the ground plane, the other end of R10 goes to the 210A pin. Both are 100K 1/8th Watt.

The new board has only ONE 100K resistor there, and it's a quarter-Watt.

I found my notes (though not the photos) of where each of the colours went on the original board. It's on a printout of the board layout from the service manual. I penned in the notation "STB" and wrote 'W-P'right next to it. Drew in the 100K resistor. And put on a couple of question marks. I had even forgotten about it, it has been so long since this whole thing started.

SO:

Should I get a 100K resistor out of the junkbox, and tack this in on the base of the one 100K resistor, and hook the other end to the white-purple wire? Or is there a better way to accomplish this?

I cannot find that STB connection on ANY of the schematics in the archives on that rectifier board. I'm going to put the toner on the white-purple wire, and track it back if I can, figure out what this thing is if I can.

I'm truly bumfuzzled, and somewhat bummed out. The rest of all of the connections are done. I've followed every bloody one of the connections back. I've soldered them all down nicely, nothing looks too bad, all the other wires are finished. I was hoping to plug in the dummy load and try to power this up tonight. Looks like that's out of the question.

All the work, everything going along so well, and then there's this ONE spare nut left.... Sigh. Figures.

The white-purple wire that was on the rectifier board pin labeled STB, runs to the AF board (X49-0008-01) to the pin also labeled STB on that board.

Any clue what STB is supposed to stand for? And what should that line carry? Looks like bias of some sort for the AF board. I'm going to check the schematic and try to figure out what this thing does, and see what I should do about it.

Interesting that neither the 520 nor the 520S even have that line...

What's REALLY annoying is that some imbecile in production DIDN'T change the numbers between two very different boards.

Gah. This is truly annoying.

OK as I understand what you are saying you are speaking in the mic and getting some flicks of ALC and when you increase the mic gain more you reach a point where you lose the flicks of ALC and as you increase the mic gain past that spot you get flicks but much higher than you would like to see. Is this correct?

Try this to see if you are losing ALC indication or losing modulation.

Flip the meter to Ip or RF and watch the meter as you perform the same increase in mic gain. See if at the same place you were losing ALC you also lose Ip or RF indication. If you do then you know it is likely a bad spot on the mic gain pot. The peaks on IP and RF meter position will be different than what you observed on ALC but dont worry about that.

If so, you lose Ip and RF like you do ALC I would try cleaning the mic gain pot as a first step.

Also what kind of ALC indication are you trying to attain on voice peaks?

What position are you trying to run the Mic gain at (3, 4, 5, 6)?

Pretty sure the STB is "Side Tone Base" Or "Side tone Bias".
It does go to Q6 which is the side tone Transistor

Yep. Via that 100K resistor, only one of which is present on this "identical" board. Identical in -stock number- perhaps but rather very different in the parts and tie-points it presents.

Found a 520SE - specific manual and schematic, which shows the correct schematic including the Side-Tone Bias line. It was in hard-copy, in a batch of paperwork that came with the machine when it was delivered to me. I hadn't gone through all of it, and when I did I found the books for the SE, and for the DG-5, and the MC-50, tucked inside a folder in the bottom of the pile.

It appears to me that all I really need to is to tack-solder another 100K resistor onto the appropriate point on this board, and tie the wire which leads to Q6 to the other end of the resistor, to fix this little problem.

Anyone disagree? Any better ideas? Since the boards are "the same" yet quite different in this one respect, I don't see a lot of other choices unless I start from scratch with another board from

BOB (!! Not Ken!! SORRY BOB!! I am hideous with names, always have been... And I still appreciate the good price on the board you sent.)

I am not really up for waiting for another mailing, sending this one back, unsoldering and re-soldering all those wires yet again... This has gone on quite long enough, so far as I am (and my WIFE is!) concerned. It's going to have to get a closed case and a clean work-area pretty soon, to get it out of the way. And avoid the wifely wrath.

Unless there are better suggestions, I'll give the modification (added resistor) a try tomorrow.

Thanks in advance.

Dave,

Each of the Kenwood hybrid operator's manuals has a specification sheet/page that states the microphone impedance value/range. This page typically is at thefront of the manual.

I am a little confused. Are you replacing a 520SE HV Rect board with one from a TS-520?

If so, the two 100k divider resistors needed for STB are not on the 520 rectifier board. If you look at the TS520 schematic and follow the 210A terminal post leads you will see the two 100k resistors. They are shown just below the Indicator Board. Physically they are mounted on a phenolic terminal strip next to one of the 6146 finals. A yellow wire from 210A feeds them and a brown wire takes the approx +105vdc and feeds the STB wire wrap post on the Audio board.

The 520, 520S and 520SE all use same RC Phase Shift Side Tone Oscillator circuit. All have an STB line that is originated from 210A on the HV rectifier board.

STB is Side Tone Bias. It should be approx +105vdc at the STB terminal on the Audio board. STB works in conjunction with KEY to forward bias Diode D3 inserted in the RC Phase Shift Network of the Side Tone Oscillator. You can Google on RC phase shift network oscillators to see how they work. You will also find a formula to use that you can plug in the RC values and calculate the frequency. In this case .012uf and 10k ohms. Some folks dont like the approx 750hz tone and change these values.

D3 is there to open and close this RC network that provides regenerative feedback from the Collector to the Base of the Q6 Oscillator. D3 switch is one of the means that they make sure that the oscillator does not run when the code key is up.

STB provides +105vdc thru a 1meg series dropping resistor to the anode of D3. KEY supplies -67vdc thru a 220k series dropping resistor to the anode of D3. So you have two voltages in parallel supplied to the anode of D3. The cathode of D3 switch is at ground potential thru a 10k resistor.

With the code key up D3 is reverse biased and turned off opening Q6 oscillator feedback path. When you press the code key Key goes to 0vdc and D3 is then forward biased by STB and the feedback path is completed. It takes STS and STE to turn on the oscillator but not relative to what STB is and what it does.

So if you have used a TS520 HV rectifier board without the two 100k divider resistors mounted outboard you will need to add them . You need to divide 210A in half to provide +105vdc at STB terminal on the Audio board. It is there in Rx and Tx modes and approx +105vdc at all times. .

Dave:

I am not an audio amp design guy. I believe the difference in the required mic specifications between the TS820 and TS830 may have to do with the Processor design and where the processor is at in the SSB signal generation path. I dont think like most specs in the TS820 manuals that it is a mistake that it does not list the same impedance range as the TS830. However, it could simply be an an oversight and that would certainly not surprise me.

The TS820 is not an RF clipper circuit. This processor is inserted right after the 1st Mic pre-amp stage and takes the audio output from it and feeds it to the processor mic amp which then inserts the audio into a Balanced Mod along with a 455khz LO signal to produce a DSBSC signal. It then processes (compresses) this signal which is ultimately fed to the actual SSB balanced modulator.

It seems that the processor mic amp would not care or see what the mic impedance presented to the 1st mic amp is. It may all have to do with the mic amp output level that is provided to the processor?

The TS-830 uses a true RF clipper that is in the IF path so mic amps and mic Z mean nothing to this design.

Both rigs use a similar single transistor mic pre-amp circuits. You can look at the component values and the active device and see some differences but as I said not a audio guy.

I think if you measure the output of each 1st mic amp you may see some difference in level for the same position of the mic gain pot? However you would think they would deal with that at the mic amp that directly feeds the processor balanced modulator and not at the 1st mic amp.

Again this is not what I know. Just suggesting it may be a reason for specifying the high Z mic for the TS820 which I understand is your question and a good one.

Maybe someday if I get curious enough I can inject 5mv 1500hz into each mic input and follow the levels thru each rig for a given mic gain pot setting. Could also connect a MC-50 on low Z setting to my TS820 and measure the levels in the processor chain and compare to when the high Z setting is used.

Another rainy day science project!

Chris if you are loading to 60 watts output now in CW mode with the new Driver tube that is progress.

If you load to 60 watts output and then flip to SSB and modulate the rig it would be normal to see no more than 15 to 20 watts on voice peaks on an average reading wattmeter. Of course audio should not sound garbled. Sometimes audio wont sound good if the receiving rig in the shack is close to the transmitting rig and is being overloaded. Have you removed ant to the receiver or turned on rf attenuator to see if it helps with the audio quality?

At 60 watts output in CW you will not see any ALC if you flip from IP back to ALC position. This is because you will have less than 30rms rf drive volts on Pin 5 of the finals at 60 watts output. 30 x 1.414 = 42 peak rf volts. Your operating bias is - 49vdc. You cannot expect +42 volts of rf drive to overcome -49 volts of bias. There can be no ALC indication if there is no grid current flowing on positive peaks of the rf drive envelope. To really understand where you are at you need to be able to measure the operating dc bias voltage and the RF drive voltage at the 6146 control grids.

When you go to USB and modulate the rig now you will get spikes of RF drive voltage at Pin 5 that will overcome the -49vdc bias offset and cause the ALC meter to deflect up scale. If you whistle in the mic may even peg the ALC indication.

Car pot level and mic gain unbalance the Balanced Modulator in different ways and can be comparing apples to oranges depending on Car level set point and mic gain set point and how hard you are talking the rig up.

As to bad audio. You could have bad audio but absent a 2 tone test an on air report would be better assessment.

As to getting power output up to approx 100 watts have you performed a good coil pack alignment as detailed in the maintenance section of your operating manual?

Could also have soft finals or low DC voltages on the finals?

Sure wish you had a means to measure RF drive levels. In 10 minutes you would know where you do not have spec RF drive at. Then it is typically relatively easy to determine what is wrong once you know what stage you are dealing with.

Absent test gear all you can do is shine a flash lite, sniff, tap and probe, mess with molex connectors, spray contact cleaner, change driver and final tubes etc. That is all fine, but at some point you have to troubleshoot by making some simple and quick measurements.

It will save you needless hours and much frustration when you can build up a modest test bench.

Ok, I tried a couple of different driver tubes now. With on RCA that appeared to be NOS, I doubled my output power to 20W, but no ALC deflection in tune. With a generic tube I am getting 60W out in CW. However, still no ALC deflection in TUN mode. No matter what the settings. The ALC meter does deflect in USB/LSB. I would say that the meter function seems normal. I get very little power out in SSB, and using a dummy load and my little FT-817 for a monitor, the audio sounds pretty crappy.

Hope this helps the trouble shooting process.

When you say you are getting 10 watts output in SSB mode are you saying when you key the mic in SSB with mic gain turned all the way down you are getting out 10 watts? OR

I am getting 10W peaks. No carrier present. I think I remember aligning the radio when I first got it. It is pretty much working ok, but with low power.

Are you saying while modulating the rig in SSB mode (speaking into the microphone with the mic gain turned up to approx 1200) that you only see about 10 watts on voice peaks?

Yes.

These are two very different things. 10 watts on voice peaks is a little low but it depends on your mic, the mic gain setting, how you are talking in to it and a little with the ballistic characteristics of your wattmeter.

If it is the former then the Balanced Modulator carrier null/balance is probably out of adjustment assuming no problem with the ring diodes. You will need to adjust TC-1 and VR-2 on the Generator board to null and balance the carrier between LSB and USB. Will need RF probe and VTVM/DMM or O-scope to do this. We can help you perform this step. Another way to do it is with a separate receiver sitting near the 520 but not as sensitive, but probably OK at this po! int to get it close.

Yes, it is balanced. See above.

If it is the later then with rig loaded to 100 watts output it is normal to see peaks of no more than 25 to 30 watts maximum on an average reading wattmeter as you modulate the rig. If you had ALC indication would tell you to adjust mic gain to keep ALC indication within middle of the black rectangular box. Your manual will tell you to keep the peaks within the upper limit of the range. This is to prevent splatter to adjacent frequencies.

Yes, got it. Just like most other SSB rigs.

With the rig in LSB or USB you should be able to key the mic or flip to send and have no RF output power until you speak in the Mic. The Car Level pot has nothing to do with this. It can be set anywhere and have no effect on SSB power output.

Yes, no power unless modulation is present.

When you say your audio is distorted are you saying your transmit audio or receive audio? If transmit then I would perform the carrier null/balance as a first step.

When I increase the mic gain, but this could be the said splatter. I am not going to worry about this until I can get the rig to put out more power and a proper ALC reading.

Yes you can use a DMM but it is not as good for peaking and nulling as an analog meter is. It will work if that is what you have. Also, depending on your DMM it may not be 10meg input and not good for much more than measuring things like dc power supply voltages and some of the tube dc voltages. Not good for getting on grids of tubes and AGC/ALC bus work. A cheap Harbor Freight has an input Z of under 1 meg and some of the Lowes/Sears/Home Depot are around 2meg. They are for electricians and not electronic work.

Got it. For peaking. I had one when I was a teenager. I think I saw it at my parents house. I have not messed with it since the 80's.

Terry K9TW

Thanks,
Chris Maness

--- In ts-520_820_530_830@yahoogroups.com, <chris@...> wrote:

Two more questions. Why would it only put out power in CW when the CAR is fully CCW (0 position)? If I increase it at all I loose all power to the antenna. At full CCW I get 10W out. This seems strange to me. However, under NO conditions do I get an ALC deflection (in TUN or CW). I have not messed with the ALC in SSB. However, I only get about 10W out in SSB too. Audio is also a bit on the crappy side. I suppose loss in linearity of the driver tube could explain the bad audio.

Can I use my modern DVM in place of a VTVM? I might have an oldy at my parent's house if they have not tossed it.

Thanks,
Chris

Chris:

I tried to respond but have not seen it yet so not sure what happened. I dont like this new format. Hard to teach old dog new tricks/.

So let me restate to make sure I fully understand.

You are telling me that you had the SG switch off, the Heaters on, in CW mode, Meter in ALC, the CAR level pot full CW or at minimum no less than at 1200 or No 5 position. When you flip to s! end and peak the Drive control thru its complete range that you get no ALC indication on any band. If that is true then most likely problem is:

Yes, you have understood me correctly I did the test 100% per your instruction. I also did the test as if I was following the tuning procedure to peak the driver as per the manual. I did this in TUN mode. Every single band showed no deflection when the CAR was at 5 and also at 10 (fully CW). I will try to get a hold of a 12BY7A and report back.

Thank you for the flow chart below.

1. Bad 12BY7A driver tube or bad dc voltages to it or bad solder connections at tube socket.

2. Bad/dirty contacts on Aux relay that switches the ALC bus voltage
3. A bad meter position switch contacts (not very common).

I would start by replacing the 12BY7A driver tube. Make sure rig is unplugged and let it set awhile to ensure voltage discharged off HV caps. Remove rig top cover to access tube on the RF board. Sometimes the ground strap can be galled and bonded to the metal shield. There is a full length split on the shield. Use a thin flat blade screw driver to spread the split. Carefully work the shield can off so you do not break the ground strap that is sandwiched between the glass envelope and metal can. When replacing the shield make sure the ground strap is placed back between the shield and the tube.

Here is where you need an RF Probe and VTVM. In 10 minutes you could measure the RF drive voltage at the control grids of the 6146 finals to see if you have RF drive greater than approx 39rms volts. Should be close to 46rms volts for full scale ALC deflection. If you are experienced with O-scope could use it as well. RF probe and VTVM are a must have if to service own Hybrid.

If new Driver tube doesnt help then try cleaning the Aux relay. Come back for the procedure for that.

In case you are interested for the above test to work you need the following:
1. Good 6146 final tubes. By good I mean good filament so there is cathode emission.
2. Good negative dc operating bias on the control grids of the finals. By good I mean voltage on control grids must switch from approx -100vdc cut off bias to approx -55vdc operating bias when you flip to Send. This is occurring as you stated you are able to set resting plate current to 60ma.

3. Good RF drive voltage at the control grids of the 6146 finals. By good I mean approx 46rms rf volts. 46 x 1.414 = 65 peak rf volts. +65 and -55 = approx +10 volts on positive peak of the drive envelope. This causes control grid to be positive with respect to the cathode and ! approx 40ua of grid current.

When the control grid of the 6146 final tubes becomes positive with respect to the cathode grid current will flow. When grid current flows the ALC amp transistor senses it and reduces the ALC bus voltage and reduces the RF drive. When the ALC bus voltage is reduced from its nominal 3.2vdc RF-1 level the ALC meter circuit sees this and drives the meter up scale. So with any hint of grid current the ALC meter should move up scale. At approx 40ua of grid current meter should be full scale.

If the Driver tube is soft could have insufficient RF voltage swing at 6146 control grids to overcome the -55vdc bias offset. For example if Driver tube is only capable of 39rms volts then 39 x 1.414 = 55 peak volts. So if RF drive is swinging the control grid to +55 volts on positive going peak of the drive envelope then +55 and -55 means Zero difference voltage and the control grid is not positive with respect to the cathode and there will be no grid current and no ALC indication.

Topic: 44440 Message: 44528

I hope you meant you set the AT230 to look at the dummy load and not the antenna?

What I think you are saying is that on 40 meters and 20 meters you can load the rig into a dummy load to approx 100 watts output, but to do that you have to have the Plate load capacitor plates fully closed.ie near full CCW position.

It sounds like not getting fixed padder caps switched in parallel with the Plate Load cap. However 20 meters doesnt use a padder. The bandswitch coupler is very different in the 520 so should not be an issue with wrong tank coil tap selected.
Did you try to load on 10 meters? It requires the lowest amount of Plate load capacitance.

The antenna SWR issue has nothing to do with problem as you are loading into the dummy load. Needs to be looked at but need to fix rig first. Probably just need to trim each leg to get it resonant in portion of 40 meter band where he wants it to be.

This is a puzzle. I need to study schematic and think about it. Perhaps someone else has a thought.

Lastly, no need to use a code key or place rig in vox. When I am testing a rig on the bench I make it as simple as possible. No need to introduce additional coax jumpers etc. Just the rig, the wattmeter, and the dummy load. Did you use the AT-230 in bypass to just have the wattmeter capability? If so, that is OK. I know folks who dont operate cw who think they have to load with a key in the jack instead of using the Send switch on the front panel.

Hi all:

Thanks for your help with Jason's tuning issues.

I went over to his station to look at his TS-520. I took my dummy load, straight key and AT230 to give us a little better set up for our efforts.

Here is what we did:
1. Hooked up the AT230 and dummy load. Set the antenna to point to the dummy load
2. Band to 40m
3. Verified that the plate idling current is 60ma.
4. Went through the typical Kenwood hybrid tune up
4a. Verified starting switch positions
4b. Tune position, ALC meter, AT230 to power
4c. Peaked drive for about 2/3 meter
4d. IP meter
4e. Dipped the plate (To this point everything on the 520 meter and the AT230 power reading looked the same as it does when I tune up my 830---It all looked normal to me.)
4f. Mode to CW. VOX on
4g. Closed the key (Even with no load the IP is showing 200ma and the power out is about

70w.)
4h. I advanced the load a bit (CW), keyed the rig and dipped the plate again. The plate current was higher but the power out was lower. No matter where I set the load/dipped the plate, the highest output was with minimum load (fully CCW).
5. Tried the same procedure on 20m. Same results
6. Advancing the carrier to 225ma with the load at minimum, plate dipped, produces 100w.
7. After this I checked Jason's antenna...the SWR is about 10:1 (he is working on that). He also has resistors on order to use to construct his own dummy load.
8. We listened around the bands a bit. The radio seems to hear fine.

So...I think the problem where he wasn't getting a dip in the plate current before (previous email) was probably because the load was fully CW instead of fully CCW at that time. Trying to tune into a 10:1 antenna was probably not helping things.

Questions:
1. Thoughts on the load issue? Seems like the load range we want is somewhere beyond the minimum of what we are getting now. It is possible that the minimum setting happens to be just the load we want but that doesn't seem right.

Both Jason and I have fairly limited technical skills working inside the radio. I've done the basic stuff (cleaned relays, performed an alignment, etc.) but that is about the limit of my experience (so far---learning acquiring test equipment as things come up.)

Thanks,
Brian (K7TKT)

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

Jason:

The best advice you got was from Bill to get a dummy load. You say you followed the TS520 instructions exactly. It does not sound like that to me.

1. Preset all the controls as listed on Page 21 Table 2. Add one control. Set the Load control to full CCW (plates fully meshed). I know you cant see them. Someday take off cover of PA cage and study whats going on here.
2. Set the Plate Idling Current to 60ma. Do that with meter in Ip, mode switch LSB/USB, mic gain turned down. Unkey the rig.
3. Set meter switch back to ALC. Set Car Level Pot to 1200. Mode switch Tune. Flip to Send and adjust the Drive control for a peak. Around 1/2 or 2/3 of full scale is a good spot to be able to see the peak. If the meter pegs then just back down the car pot and re-peak the Drive control. Now you have set the the RF drive voltage to the 6146 control grids to maximum and ready to move on to the initial plate current dip.
4. Place meter in Ip position. Flip to Send and adjust Tune control for a minimum or dip in plate current. You will not see much plate current perhaps 50ma to 60ma. Dip may not be very pronounced. On a wattmeter would see approx 10 to 15 watts peak. Return to Rec or Stand-by (unkey the rig). You are adjusting the pi-network (tank circuit) to resonance at this step with the Screen Grid voltage reduced to about 1/2 normal. This allows you to get the final tubes ready for full SG voltage and no concern about the plate current being pegged high when you first key the rig in CW mode should it be off resonance. Later you may

choose to load in CW mode from the outset, but not a good idea at this time of your understanding and experience.
5. If you do not have an external wattmeter then place the panel meter in the RF position. In this position none of the meter scales are used. You are looking at a sample of RF voltage being applied to your dummy load. This is relative power and not watts. Just looking for a maximum level on the meter.
6. Flip to Send and note the meter indication. Dont leave rig keyed for more than 5 to 10 seconds. If it is very low or very high adjust the RF sensitivity pot on left side of rig to get meter indicator at approx 1/2 to 2/3 scale. Unkey the rig.
7. For the next steps do not leave rig keyed more than approx 5 to 10 seconds at a time. You are going to be opening the plates of the Load capacitor a little at a time by turning the control clockwise and adjusting the Tune capacitor for maximum RF relative power indication. As you open the plates (turn Load control CW) you are coupling load and beginning to transfer tank circuit circulating current thru the dummy load resistor instead of shunting it thru the Load capacitor.
8. Turn the Load capacitor control a few degrees clockwise (open the plates) . Flip to Send and adjust the Tune capacitor for maximum RF relative power indication. Unkey the rig. If meter pegs at any time adjust the RF sensitivity pot to bring meter indication back around 2/3 scale.
9. Turn the Load capacitor control a few more degrees clockwise. Flip to Send and adjust Tune capacitor for maximum RF indication again. Unkey the rig.
10. Repeat this two step process until you cannot get anymore RF relative power indication. Make sure you note where the peak is at each time. You can read it off the black plate current scale. If you have opened the plates of the Load capacitor too much (too far clockwise) the RF relative power indication will start to fall off.
11. Place meter back to Ip.
12. Flip to Send and note IP reading. It should be approx 200ma. If it is you are done and ready for CW and SSB transmission.
13. If it is much above 200 ma say 225 ma to 250 ma (not likely it will be) then turn the Load control very slightly back CCW (close the plates a little) . Place meter back to RF position . Flip to Send and adjust the Tune control for maximum RF indication. Unkey the rig and place meter back to Ip.
14, Flip to Send and check IP again. Should now be closer to 200 ma and you are done. Unkey the rig. Read the section on CW and SSB transmission.

When you get better and more comfortable with this procedure you will simply at Step 8 alternately adjust the Load and Tune capacitors for maximum RF relative power indication or maximum RF output power on your external wattmeter (approx 100 watts with exception of 10 meters) at one step as you can do it quickly. Then you will check Ip to make sure not exceeding approx 200ma. It wont be a stepped procedure just a smooth one step loading.

An external wattmeter makes it nice because you can leave the panel meter in IP and just tune for approx 100 watts output and see at the same time if exceeding 200ma. It is much easier to see RF output peaks rather than plate current dip in a Class AB-1 transmitter. Also wattmeter is likely to have different ballistic characteristics than your panel meter making it easier to see changes. Also, if you see unusually high or low wattage you know there is a problem. Using the RF relative power meter and IP meter you have no idea if there is a problem. It would take the average ham a little time using just these two meters to realize that the PL-259 was not connected. With a wattmeter you know it instantly. Just makes loading a breeze for new folks.

Print this and pull it out when you get your dummy load. Remember SWR has nothing to do with your Car Level Pot.

Also if you have any reasonable level of RF output power from your rig you should be able to adjust the sensitivity pot on your SWR bridge to full scale in Forward position and then flip to Reflected and read the SWR. It doesnt care how you have loaded the rig. It just needs enough rf to get full scale deflection in Forward position and typically that is not much power. If you had RF output from your rig then it sounds like your SWR bridge is defective and not a rig problem or you have an open down stream of the SWR bridge and and will see very high reflected.

Sorry so long but essentially restating the TS520 manual.

Terry K9TW

Hey guys,

I just got into amateur radio last month. I got my first HF rig at an estate sale for an old ham who passed away. I got the TS-520. The amateurs at the sale said the guy took really good care of his stuff and that this rig was recently serviced. I took it home and began to set it up.

I am operating on 40 meters with a dipole. All I have is this rig, a SWR meter, and the dipole, no other equipment for HF.

I ran through the tuning procedure in the Kenwood manual, I followed it exactly and everything went fine up to dipping the plate. The needle shows 60 ma, In order for ALC to peak, CAR needs to be set at 1.5 (anything higher and the needle pegs), and the plate reading is 80 ma, but will not dip when I turn the plate dial (which is centered on the band as per the instructions). I have also followed the tuning instructions by Ken, K4EAA and the same result happens.

I do not know for sure what my antenna's SWR is, when I attempt to use my SWR meter, it will not calibrate. I know the meter works, so I was concerned is may be an issue with the TS-520.

I have looked through the groups past posts, as well as Google, and I can't seem to find an answer to my problem. This post is the result of at least 3 days of failed research. Any help would be greatly appreciated. I can tune stations in just fine on 40 meters, but they just can't hear me (which is understandable for this situation).

Thank you guys in advance,

Jason, K7BOG

Ok, update. I tried the 160/80/40m with the new driver. I get ALC deflection in TUN finally. I get a peak of about 40% of full scale in 160m. I get 20% of full scale in 80m, and it just barley moves at the DRIVE peak on 40m. Not even a quiver at 20m. So I am thinking my best driver is still on the flat side. I think there is a problem though. I only get deflection when the CAR is set to fully CCW. That makes me think something is broken, and will still be an issue when I get a strong driver tube.

Chris
Ok, I tried a couple of different driver tubes now. With on RCA that appeared to be NOS, I doubled my output power to 20W, but no ALC deflection in tune. With a generic tube I am getting 60W out in CW. However, still no ALC deflection in TUN mode. No matter what the settings. The ALC meter does deflect in USB/LSB. I would say that the meter function seems normal. I get very little power out in SSB, and using a dummy load and my little FT-817 for a monitor, the audio sounds pretty crappy.

Hope this helps the trouble shooting process.

44531. Re: [TS-520_820_530_830] RE: Strange Behavior of the Carrier Control?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-14 16:35:02 UTC
From: Chris Maness
Topic: 44446 Message: 44531

Another update. On air reports state my audio sounds distorted. It does sound better with the ATT on my monitor radio, but I am getting bad audio reports from distant stations. I am so bummed. This radio has the nicest receive audio I have ever heard on SSB. I hope I can get this ironed out.

Thanks,
Chris KQ6UP

44532. 12BY7A Brand Recommendations?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-14 16:36:43 UTC

I need a new driver tube, and I see that there are many brands on the auction site. What brand/brands play well with the TS-520S?

Thanks,
Chris Maness KQ6UP

44533. Re: [TS-520_820_530_830] RE: Strange Behavior of the Carrier Control?

Question. Would the fact that I am using a MC-30S mike cause an issue? I
don't own the original MC-50.

Thanks,
Chris KQ6UP

Chris,

Remember, all these microphones are getting OLD and many do have bad elements. Also, "on air audio reports" are suspect. Terry or whoever mentioned it is very correct in asking you to check yourself on a monitor receiver. If you have the opportunity, try another microphone. The "treasured" MC-50 you buy may or may not be any better than what you have. I have a shelf full of good looking microphones that sound VERY bad as the elements are shot.

I have the best luck monitoring myself by transmitting into a dummy load and trailing a short piece of any wire along the shelf from the monitor receiver. ALWAYS use headphones when monitoring yourself so you can hear the signal well. Make SURE you are on the same frequency as your transmitting rig (tune through the signal and see if you can hear a "sweet spot").

The next best test is to ask a ham close to you that knows what you sound like "live" to listen and comment. This is still VERY objective, as some like really bassy sound, some like more highs for "clarity". Each will likely give you a different report. You are the chief engineer and have to decide when you sound good to yourself!! Last tip: I often ask my wife of 45 years to put on the headphones and tell me if it sounds like me on the monitor receiver. She knows what I sound like best :>).

Hi Terry:

Thank you.

Sorry...Yes, TS-520 to AT230 to dummy load for all tuning activities. I like to watch the power meter in actual watts output when I'm tuning. Also disregard the antenna reference...this is not the right board for that but it might explain some of the earlier odd readings Jason was getting since he was trying to tune into a load that was nowhere close to 50 ohm at frequency.

Yes, on 20m and 40m maximum output was acheived with minimum load (full ccw) and plate dipped. At 200ma current output was about 70w. It acts like there is too much load even at minimum. Giving it more load and redipping the plate results in less power out. Also, at minimum load and dipped I could get 100w by increasing the carrier so that my plate current was 225ma.

Sorry we didn't try other bands (10m). I suppose plate ma and watts out at the best load on each band would be useful to figure this out. Assuming it is OK with Jason, I could go back over sometime to do that.

Lastly, about the key. I guess I have something to learn here. When I tune up I use the send switch when in tune mode. However once I am ready to adjust the load and have to switch the mode to CW, putting the transceiver in send only shows idle current. I have to close the key to get full output so that I can adjust the load and re-dip the plate at 225ma (for my TS-830). If I don't put it in VOX mode then I have to flip the switch to send AND close the key to key the transmitter while I'm trying to dip. (I'm not that coordinated so I use the VOX). Anyway, not sure how I would do that without a key. This is a side issue but if I'm doing it wrong I'd like to know.

Thanks again for all of your help,
  Brian (K7TKT)

Subject: RE: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

I hope you meant you set the AT230 to look at the dummy load and not the antenna?

What I think you are saying is that on 40 meters and 20 meters you can load the rig into a dummy load to approx 100 watts output, but to do that you have to have the Plate load capacitor plates fully closed.ie near full CCW position.

It sounds like not getting fixed padder caps switched in parallel with the Plate Load cap. However 20 meters doesnt use a padder. The bandswitch coupler is very different in the 520 so should not be an issue with wrong tank coil tap selected.

Did you try to load on 10 meters? It requires the lowest amount of Plate load capacitance.

The antenna SWR issue has nothing to do with problem as you are loading into the dummy load. Needs to be looked at but need to fix rig first. Probably just need to trim each leg to get it resonant in portion of 40 meter band where he wants it to be.

This is a puzzle. I need to study schematic and think about it. Perhaps someone else has a thought.

Lastly, no need to use a code key or place rig in vox. When I am testing a rig on the bench I make it as simple as possible. No need to introduce additional coax jumpers etc. Just the rig, the wattmeter, and the dummy load. Did you use the AT-230 in bypass to just have the wattmeter capability? If so, that is OK. I know folks who dont operate cw who think they have to load with a key in the jack instead of using the Send switch on the front panel.

Hi all:

Thanks for your help with Jason's tuning issues.

I went over to his station to look at his TS-520. I took my dummy load, straight key and AT230 to give us a little better set up for our efforts.

Here is what we did:
1. Hooked up the AT230 and dummy load. Set the antenna to point to the dummy load
2. Band to 40m
3. Verified that the plate idling current is 60ma.
4. Went through the typical Kenwood hybrid tune up
4a. Verified starting switch positions
4b. Tune position, ALC meter, AT230 to power
4c. Peaked drive for about 2/3 meter
4d. IP meter
4e. Dipped the plate (To this point everything on the 520 meter and the AT230 power reading looked the same as it does when I tune up my 830---It all looked normal to me.)
4f. Mode to CW. VOX on

4g. Closed the key (Even with no load the IP is showing 200ma and the power out is about 70w.)
4h. I advanced the load a bit (CW), keyed the rig and dipped the plate again. The plate current was higher but the power out was lower. No matter where I set the load/dipped the plate, the highest output was with minimum load (fully CCW).
5. Tried the same procedure on 20m. Same results
6. Advancing the carrier to 225ma with the load at minimum, plate dipped, produces 100w.
7. After this I checked Jason's antenna...the SWR is about 10:1 (he is working on that).
 He also has resistors on order to use to construct his own dummy load.

8. We listened around the bands a bit. The radio seems to hear fine.

So...I think the problem where he wasn't getting a dip in the plate current before (previous email) was probably because the load was fully CW instead of fully CCW at that time. Trying to tune into a 10:1 antenna was probably not helping things.

Questions:
1. Thoughts on the load issue? Seems like the load range we want is somewhere beyond the minimum of what we are getting now. It is possible that the minimum setting happens to be just the load we want but that doesn't seem right.

Both Jason and I have fairly limited technical skills working inside the radio. I've done the basic stuff (cleaned relays, performed an alignment, etc.) but that is about the limit of my experience (so far---learning acquiring test equipment as things come up.)

Thanks,
  Brian (K7TKT)

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

Jason:

The best advice you got was from Bill to get a dummy load. You say you followed the TS520 instructions exactly. It does not sound like that to me.

1. Preset all the controls as listed on Page 21 Table 2. Add one control. Set the Load control to full CCW (plates fully meshed). I know you cant see them. Someday take off cover of PA cage and study whats going on here.
2. Set the Plate Idling Current to 60ma. Do that with meter in Ip, mode switch LSB/USB, mic gain turned down. Unkey the rig.
3. Set meter switch back to ALC. Set Car Level Pot to 1200. Mode switch Tune. Flip to Send and adjust the Drive control for a peak. Around 1/2 or 2/3 of full scale is a good spot to be able to see the peak. If the meter pegs then just back down the car pot and re-peak the Drive control. Now you have set the the RF drive voltage to the 6146 control grids to maximum and ready to move on to the initial plate current dip.
4. Place meter in Ip position. Flip to Send and adjust Tune control for a minimum or dip in plate current. You will not see much plate current perhaps 50ma to 60ma. Dip may not be very pronounced. On a wattmeter would see approx 10 to 15 watts peak. Return to Rec or Stand-by (unkey the rig). You are adjusting the pi-network (tank circuit) to resonance at this step with the Screen Grid voltage reduced to about 1/2 normal. This allows you to get the final tubes ready for full SG voltage and no concern about the plate current being pegged high when you first key the rig in CW mode should it be off resonance. Later you may choose to load in CW mode from the outset, but not a good idea at this time of your understanding and experience.
5. If you do not have an external wattmeter then place the panel meter in the RF position. In this position none of the meter scales are used. You are looking at a sample of RF voltage being applied to your dummy load. This is relative power and not watts. Just looking for a maximum level on the meter.
6. Flip to Send and note the meter indication. Dont leave rig keyed for more than 5 to 10 seconds. If it is very low or very high adjust the RF sensitivity pot on left side of rig to get meter indicator at approx 1/2 to 2/3 scale. Unkey the rig.

7. For the next steps do not leave rig keyed more than approx 5 to 10 seconds at a time. You are going to be opening the plates of the Load capacitor a little at a time by turning the control clockwise and adjusting the Tune capacitor for maximum RF relative power indication. As you open the plates (turn Load control CW) you are coupling load and beginning to transfer tank circuit circulating current thru the dummy load resistor instead of shunting it thru the Load capacitor.
8. Turn the Load capacitor control a few degrees clockwise (open the plates) . Flip to Send and adjust the Tune capacitor for maximum RF relative power indication. Unkey the rig. If meter pegs at any time adjust the RF sensitivity pot to bring meter indication back around 2/3 scale.
9. Turn the Load capacitor control a few more degrees clockwise. Flip to Send and adjust Tune capacitor for maximum RF indication again. Unkey the rig.
10. Repeat this two step process until you cannot get anymore RF relative power indication. Make sure you note where the peak is at each time. You can read it off the black plate current scale. If you have opened the plates of the Load capacitor too much (too far clockwise) the RF relative power indication will start to fall off.
11. Place meter back to Ip.
12. Flip to Send and note IP reading. It should be approx 200ma. If it is you are done and ready for CW and SSB transmission.
13. If it is much above 200 ma say 225 ma to 250 ma (not likely it will be) then turn the Load control very slightly back CCW (close the plates a little) . Place meter back to RF position . Flip to Send and adjust the Tune control for maximum RF indication. Unkey the rig and place meter back to Ip.
14, Flip to Send and check IP again. Should now be closer to 200 ma and you are done. Unkey the rig. Read the section on CW and SSB transmission.

When you get better and more comfortable with this procedure you will simply at Step 8 alternately adjust the Load and Tune capacitors for maximum RF relative power indication or maximum RF output power on your external wattmeter (approx 100 watts with exception of 10 meters) at one step as you can do it quickly. Then you will check Ip to make sure not exceeding approx 200ma. It wont be a stepped procedure just a smooth one step loading.

An external wattmeter makes it nice because you can leave the panel meter in IP and just tune for approx 100 watts output and see at the same time if exceeding 200ma. It is much easier to see RF output peaks rather than plate current dip in a Class AB-1 transmitter. Also wattmeter is likely to have different ballistic characteristics than your panel meter making it easier to see changes. Also, if you see unusually high or low wattage you know there is a problem. Using the RF relative power meter and IP meter you have no idea if there is a problem. It would take the average ham a little time using just these two meters to realize that the PL-259 was not connected. With a wattmeter you know it instantly. Just makes loading a breeze for new folks.

Print this and pull it out when you get your dummy load. Remember SWR has nothing to do with your Car Level Pot.

Also if you have any reasonable level of RF output power from your rig you should be able to adjust the sensitivity pot on your SWR bridge to full scale in Forward position and then flip to Reflected and read the SWR. It doesnt care how you have loaded the rig. It just needs enough rf to get full scale deflection in Forward position and typically that is not much power. If you had RF output from your rig then it sounds like your SWR bridge is defective and not a rig problem or you have an open down stream of the SWR bridge and and

will see very high reflected.

Sorry so long but essentially restating the TS520 manual.

Hi Terry

Don't know if you keep separate files on posters,but here goes

Were we left off was i had only a bad audio hum and no dial light on my
Ebay special.
Update

I now have a good working audio board and dial light display and good
audio output from the test's you last asked me to do are now fine
No meter movement,but loud.
The problems are now as follows.
Sidetone fine and good audio
Moni--i can hear it but very very low,,volume turned to full output.
Calibration,can hear it but very very low,,,volume turned to full
On my SG audio good,but only S-3 meter reading.
I can hear 40 meter strong signals at night,but very very low audio.

On transmit,i can only get the 60ma reading and that's it,no output.
All voltages on the finals are fine.
All voltages on the connector's are fine.

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4 RF amps flowing thru the 50 ohm dummy load.

This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.

After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.

Read the very last note in the TS-830 loading procedure. It tells you after they have taught you dip and load you dont have to use it as it isnt best or easiest way to load a Class AB1 linear amp!

It directs you to place meter in RF position and Flip to Send and alternately adjust the plate Load and Tune controls for maximum indicated relative power (RF voltage).

With your wattmeter in line leave your TS830 meter in IP. Now after making that initial plate current dip in Tune mode flip to Send in CW mode and alternately adjust Plate Load and Plate tune controls for approx 100watts output.

Your wattmeter will be far more sensitive to any changes you make than your IP meter. You will quickly be able to find the combination that gives you max rf output power. Take a quick look at IP and it should be close to 225ma. If a little over dont worry about it as 265ma is the real limit.

Lastly, if you are having to increase the Car level at the late stage of tuning you are not setting it high enough in the early Drive control peaking step. There is no reason to have to do this. When you peak the Drive give yourself something to look at. If you peg the ALC meter just reduce the Car level pot to get it off the peg.

Hi Terry:

Thank you.

Sorry...Yes, TS-520 to AT230 to dummy load for all tuning activities. I like to watch the power meter in actual watts output when I'm tuning. Also disregard the antenna reference...this is not the right board for that but it might explain some of the earlier odd readings Jason was getting since he was trying to tune into a load that was nowhere close to 50 ohm at frequency.

Yes, on 20m and 40m maximum output was acheived with minimum load (full ccw) and plate dipped. At 200ma current output was about 70w. It acts like there is too much load even at minimum. Giving it more load and redipping the plate results in less power out. Also, at minimum load and dipped I could get 100w by increasing the carrier so that my plate current was 225ma.

Sorry we didn't try other bands (10m). I suppose plate ma and watts out at the best load on each band would be useful to figure this out. Assuming it is OK with Jason, I could go back over sometime to do that.

Lastly, about the key. I guess I have something to learn here. When I tune up I use the send switch when in tune mode. However once I am ready to adjust the load and have to switch the mode to CW, putting the transceiver in send only shows idle current. I have to close the key to get full output so that I can adjust the load and re-dip the plate at 225ma (for my TS-830). If I don't put it in VOX mode then I have to flip the switch to send AND close the key to key the transmitter while I'm trying to dip. (I'm not that coordinated so I use the VOX). Anyway, not sure how I would do that without a key. This is a side issue but if I'm doing it wrong I'd like to know.

Thanks again for all of your help,
Brian (K7TKT)

Subject: RE: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

I hope you meant you set the AT230 to look at the dummy load and not the antenna?

What I think you are saying is that on 40 meters and 20 meters you can load the rig into a dummy load to approx 100 watts output, but to do that you have to have the Plate load capacitor plates fully closed.ie near full CCW position.

It sounds like not getting fixed padder caps switched in parallel with the Plate Load cap. However 20 meters doesnt use a padder. The bandswitch coupler is very different in the 520 so should not be an issue with wrong tank coil tap selected.
Did you try to load on 10 meters? It requires the lowest amount of Plate load capacitance.

The antenna SWR issue has nothing to do with problem as you are loading into the dummy load. Needs to be looked at but need to fix rig first. Probably just need to trim each leg to get it resonant in portion of 40 meter band where he wants it to be.

This is a puzzle. I need to study schematic and think about it. Perhaps someone else has a thought.

Lastly, no need to use a code key or place rig in vox. When I am testing a rig on the bench I make it as simple as possible. No need to introduce additional coax jumpers etc. Just the rig, the wattmeter, and the dummy load. Did you use the AT-230 in bypass to just have the wattmeter capability? If so, that is OK. I know folks who dont operate cw who think they have to load with a key in the jack instead of using the Send switch on the front panel.

Hi all:

Thanks for your help with Jason's tuning issues.

I went over to his station to look at his TS-520. I took my dummy load, straight key and AT230 to give us a little better set up for our efforts.

Here is what we did:
1. Hooked up the AT230 and dummy load. Set the antenna to point to the dummy load
2. Band to 40m
3. Verified that the plate idling current is 60ma.
4. Went through the typical Kenwood hybrid tune up
4a. Verified starting switch positions
4b. Tune position, ALC meter, AT230 to power
4c. Peaked drive for about 2/3 meter
4d. IP meter
4e. Dipped the plate (To this point everything on the 520 meter and the AT230 power reading looked the same as it does when I tune up my 830---It all looked normal to me.)
4f. Mode to CW. VOX on
4g. Closed the key (Even with no load the IP is showing 200ma and the power out is about 70w.)
4h. I advanced the load a bit (CW), keyed the rig and dipped the plate again. The plate current was higher but the power out was lower. No matter where I set the load/dipped the plate, the highest output was with minimum load (fully CCW).
5. Tried the same procedure on 20m. Same results
6. Advancing the carrier to 225ma with the load at minimum, plate dipped, produces 100w.
7. After this I checked Jason's antenna...the SWR is about 10:1 (he is working on that). He also has resistors on order to use to construct his own dummy load.

8. We listened around the bands a bit. The radio seems to hear fine.

So...I think the problem where he wasn't getting a dip in the plate current before (previous email) was probably because the load was fully CW instead of fully CCW at that time. Trying to tune into a 10:1 antenna was probably not helping things.

Questions:
1. Thoughts on the load issue? Seems like the load range we want is somewhere beyond the minimum of what we are getting now. It is possible that the minimum setting happens to be just the load we want but that doesn't seem right.

Both Jason and I have fairly limited technical skills working inside the radio. I've done the basic stuff (cleaned relays, performed an alignment, etc.) but that is about the limit of my experience (so far---learning acquiring test equipment as things come up.)

Thanks,
Brian (K7TKT)

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

Jason:

The best advice you got was from Bill to get a dummy load. You say you followed the TS520 instructions exactly. It does not sound like that to me.

1. Preset all the controls as listed on Page 21 Table 2. Add one control. Set the Load control to full CCW (plates fully meshed). I know you cant see them. Someday take off cover of PA cage and study whats going on here.
2. Set the Plate Idling Current to 60ma. Do that with meter in Ip, mode switch LSB/USB, mic gain turned down. Unkey the rig.
3. Set meter switch back to ALC. Set Car Level Pot to 1200. Mode switch Tune. Flip to Send and adjust the Drive control for a peak. Around 1/2 or 2/3 of full scale is a good spot to be able to see the peak. If the meter pegs then just back down the car pot and re-peak the Drive control. Now you have set the the RF drive voltage to the 6146 control grids to maximum and ready to move on to the initial plate current dip.
4. Place meter in Ip position. Flip to Send and adjust Tune control for a minimum or dip in plate current. You will not see much plate current perhaps 50ma to 60ma. Dip may not be very pronounced. On a wattmeter would see approx 10 to 15 watts peak. Return to Rec or Stand-by (unkey the rig). You are adjusting the pi-network (tank circuit) to resonance at this step with the Screen Grid voltage reduced to about 1/2 normal. This allows you to get the final tubes ready for full SG voltage and no concern about the plate current being pegged high when you first key the rig in CW mode should it be off resonance. Later you may choose to load in CW mode from the outset, but not a good idea at this time of your understanding and experience.
5. If you do not have an external wattmeter then place the panel meter in the RF position. In this position none of the meter scales are used. You are looking at a sample of RF voltage being applied to your dummy load. This is relative power and not watts. Just looking for a maximum level on the meter.
6. Flip to Send and note the meter indication. Dont leave rig keyed for more than 5 to 10

seconds. If it is very low or very high adjust the RF sensitivity pot on left side of rig to get meter indicator at approx 1/2 to 2/3 scale. Unkey the rig.
7. For the next steps do not leave rig keyed more than approx 5 to 10 seconds at a time. You are going to be opening the plates of the Load capacitor a little at a time by turning the control clockwise and adjusting the Tune capacitor for maximum RF relative power indication. As you open the plates (turn Load control CW) you are coupling load and beginning to transfer tank circuit circulating current thru the dummy load resistor instead of shunting it thru the Load capacitor.
8. Turn the Load capacitor control a few degrees clockwise (open the plates) . Flip to Send and adjust the Tune capacitor for maximum RF relative power indication. Unkey the rig. If meter pegs at any time adjust the RF sensitivity pot to bring meter indication back around 2/3 scale.
9. Turn the Load capacitor control a few more degrees clockwise. Flip to Send and adjust Tune capacitor for maximum RF indication again. Unkey the rig.
10. Repeat this two step process until you cannot get anymore RF relative power indication. Make sure you note where the peak is at each time. You can read it off the black plate current scale. If you have opened the plates of the Load capacitor too much (too far clockwise) the RF relative power indication will start to fall off.
11. Place meter back to Ip.
12. Flip to Send and note IP reading. It should be approx 200ma. If it is you are done and ready for CW and SSB transmission.
13. If it is much above 200 ma say 225 ma to 250 ma (not likely it will be) then turn the Load control very slightly back CCW (close the plates a little) . Place meter back to RF position . Flip to Send and adjust the Tune control for maximum RF indication. Unkey the rig and place meter back to Ip.
14, Flip to Send and check IP again. Should now be closer to 200 ma and you are done. Unkey the rig. Read the section on CW and SSB transmission.

When you get better and more comfortable with this procedure you will simply at Step 8 alternately adjust the Load and Tune capacitors for maximum RF relative power indication or maximum RF output power on your external wattmeter (approx 100 watts with exception of 10 meters) at one step as you can do it quickly. Then you will check Ip to make sure not exceeding approx 200ma. It wont be a stepped procedure just a smooth one step loading.

An external wattmeter makes it nice because you can leave the panel meter in IP and just tune for approx 100 watts output and see at the same time if exceeding 200ma. It is much easier to see RF output peaks rather than plate current dip in a Class AB-1 transmitter. Also wattmeter is likely to have different ballistic characteristics than your panel meter making it easier to see changes. Also, if you see unusually high or low wattage you know there is a problem. Using the RF relative power meter and IP meter you have no idea if there is a problem. It would take the average ham a little time using just these two meters to realize that the PL-259 was not connected. With a wattmeter you know it instantly. Just makes loading a breeze for new folks.

Print this and pull it out when you get your dummy load. Remember SWR has nothing to do with your Car Level Pot.

Also if you have any reasonable level of RF output power from your rig you should be able to adjust the sensitivity pot on your SWR bridge to full scale in Forward position and then flip to Reflected and read the SWR. It doesnt care how you have loaded the rig. It just needs enough rf to get full scale deflection in Forward position and typically that is not much power. If you had RF output from your rig then it sounds like your SWR bridge is

defective and not a rig problem or you have an open down stream of the SWR bridge and and will see very high reflected.

Sorry so long but essentially restating the TS520 manual.

Terry K9TW

Hey guys,

I just got into amateur radio last month. I got my first HF rig at an estate sale for an old ham who passed away. I got the TS-520. The amateurs at the sale said the guy took really good care of his stuff and that this rig was recently serviced. I took it home and began to set it up.

I am operating on 40 meters with a dipole. All I have is this rig, a SWR meter, and the dipole, no other equipment for HF.

I ran through the tuning procedure in the Kenwood manual, I followed it exactly and everything went fine up to dipping the plate. The needle shows 60 ma, In order for ALC to peak, CAR needs to be set at 1.5 (anything higher and the needle pegs), and the plate reading is 80 ma, but will not dip when I turn the plate dial (which is centered on the band as per the instructions). I have also followed the tuning instructions by Ken, K4EAA and the same result happens.

I do not know for sure what my antenna's SWR is, when I attempt to use my SWR meter, it will not calibrate. I know the meter works, so I was concerned is may be an issue with the TS-520.

I have looked through the groups past posts, as well as Google, and I can't seem to find an answer to my problem. This post is the result of at least 3 days of failed research. Any help would be greatly appreciated. I can tune stations in just fine on 40 meters, but they just can't hear me (which is understandable for this situation).

Thank you guys in advance,

Jason, K7BOG

The 520 needs a high Z mic. The MC30 is a 500 ohm low Z mic and intended for close talking in mobile applications. It is not designed for your 520. Even a MC35 isnt going to sound as good as a MC50 or MC60.

An Astatic D104 and a Shure 444D are both good mics for your 520.

Another update. On air reports state my audio sounds distorted. It does sound better with the ATT on my monitor radio, but I am getting bad audio reports from distant stations. I am so bummed. This radio has the nicest receive audio I have ever heard on SSB. I hope I can get this ironed out.

Thanks,
Chris KQ6UP

On Sat, Sep 14, 2013 at 8:10 AM, Chris Maness <chris@...> wrote:

Ok, update. I tried the 160/80/40m with the new driver. I get ALC deflection in TUN finally. I get a peak of about 40% of full scale in 160m. I get 20% of full scale in 80m, and it just barley moves at the DRIVE peak on 40m. Not even a quiver at 20m. So I am thinking my best driver is still on the flat side. I think there is a problem though. I only get deflection when the CAR is set to fully CCW. That makes me think something is broken, and will still be an issue when I get a strong driver tube.

Chris

Ok, I tried a couple of different driver tubes now. With on RCA that appeared to be NOS, I doubled my output power to 20W, but no ALC deflection in tune. With a generic tube I am getting 60W out in CW. However, still no ALC deflection in TUN mode. No matter what the settings. The ALC meter does deflect in USB/LSB. I would say that the meter function seems normal. I get very little power out in SSB, and using a dummy load and my little FT-817 for a monitor, the audio sounds pretty crappy.

Hope this helps the trouble shooting process.

On Wed, Sep 11, 2013 at 2:44 PM, Chris Maness <chris@...> wrote:

When you say you are getting 10 watts output in SSB mode are you saying when you key the mic in SSB with mic gain turned all the way down you are getting out 10 watts? OR

I am getting 10W peaks. No carrier present. I think I remember aligning the radio when I first got it. It is pretty much working ok, but with low power.

Are you saying while modulating the rig in SSB mode (speaking into the microphone with the mic gain turned up to approx 1200) that you only see about 10 watts on voice peaks?

Yes.

These are two very different things. 10 watts on voice peaks is a little low but it depends on your mic, the mic gain setting, how you are talking in to it and a little with the ballistic characteristics of your wattmeter.

If it is the former then the Balanced Modulator carrier null/balance is probably out of adjustment assuming no problem with the ring diodes. You will need to adjust TC-1 and VR-2 on the Generator board to null and balance the carrier between LSB and USB. Will need RF probe and VTVM/DMM or O-scope to do this. We can help you perform this step. Another way to do it is with a separate receiver sitting near the 520 but not as sensitive, but probably OK at this po! int to get it close.

Yes, it is balanced. See above.

If it is the later then with rig loaded to 100 watts output it is normal to see peaks of no more than 25 to 30 watts maximum on an average reading wattmeter as you modulate the rig. If you had ALC indication would tell you to adjust mic gain to keep ALC indication within middle of the black rectangular box. Your manual will tell you to keep the peaks within the upper limit of the range. This is to prevent splatter to adjacent frequencies.

Yes, got it. Just like most other SSB rigs.

With the rig in LSB or USB you should be able to key the mic or flip to send and have no RF output power until you speak in the Mic. The Car Level pot has nothing to do with this. It can be set anywhere and have no effect on SSB power output.

Yes, no power unless modulation is present.

When you say your audio is distorted are you saying your transmit audio or receive audio? If transmit then I would perform the carrier null/balance as a first step.

When I increase the mic gain, but this could be the said splatter. I am not going to worry about this until I can get the rig to put out more power and a proper ALC reading.

Yes you can use a DMM but it is not as good for peaking and nulling as an analog meter is. It will work if that is what you have. Also, depending on your DMM it may not be 10meg input and not good for much more than measuring things like dc power supply voltages and some of the tube dc voltages. Not good for getting on grids of tubes and AGC/ALC bus work. A cheap Harbor Freight has an input Z of under 1 meg and some of the Lowes/Sears/Home Depot are around 2meg. They are for electricians and not electronic work.

Got it. For peaking. I had one when I was a teenager. I think I saw it at my parents house. I have not messed with it since the 80's.

Terry K9TW

--- In ts-520_820_530_830@yahoogroups.com, <chris@...> wrote:

Two more questions. Why would it only put out power in CW when the CAR is fully CCW (0 position)? If I increase it at all I loose all power to the antenna. At full CCW I get 10W out. This seems strange to me. However, under NO conditions do I get an ALC deflection (in TUN or CW). I have not messed with the ALC in SSB. However, I only get about 10W out in SSB too. Audio is also a bit on the crappy side. I suppose loss in linearity of the driver tube could explain the bad audio.

Can I use my modern DVM in place of a VTVM? I might have an oldy at my parent's house if they have not tossed it.

Thanks,
Chris

Chris:

I tried to respond but have not seen it yet so not sure what happened. I dont like this new format. Hard to teach old dog new tricks/.

So let me restate to make sure I fully understand.

You are telling me that you had the SG switch off, the Heaters on, in CW mode, Meter in ALC, the CAR level pot full CW or at minimum no less than at 1200 or No 5 position. When you flip to s! end and peak the Drive control thru its complete range that you get no ALC indication on any band. If that is true then most likely problem is:

Yes, you have understood me correctly I did the test 100% per your instruction. I also did the test as if I was following the tuning procedure to peak the driver as per the manual. I did this in TUN mode. Every single band showed no deflection when the CAR was at 5 and also at 10 (fully CW). I will try to get a hold of a 12BY7A and report back.

Thank you for the flow chart below.

1. Bad 12BY7A driver tube or bad dc voltages to it or bad solder connections at tube socket.

2. Bad/dirty contacts on Aux relay that switches the ALC bus voltage
3. A bad meter position switch contacts (not very common).

I would start by replacing the 12BY7A driver tube. Make sure rig is unplugged and let it set awhile to ensure voltage discharged off HV caps. Remove rig top cover to access tube on the RF board. Sometimes the ground strap can be galled and bonded to the metal shield. There is a full length split on the shield. Use a thin flat blade screw driver to spread

the split. Carefully work the shield can off so you do not break the ground strap that is sandwiched between the glass envelope and metal can. When replacing the shield make sure the ground strap is placed back between the shield and the tube.

Here is where you need an RF Probe and VTVM. In 10 minutes you could measure the RF drive voltage at the control grids of the 6146 finals to see if you have RF drive greater than approx 39rms volts. Should be close to 46rms volts for full scale ALC deflection. If you are experienced with O-scope could use it as well. RF probe and VTVM are a must have if to service own Hybrid.

If new Driver tube doesnt help then try cleaning the Aux relay. Come back for the procedure for that.

In case you are interested for the above test to work you need the following:
1. Good 6146 final tubes. By good I mean good filament so there is cathode emission.
2. Good negative dc operating bias on the control grids of the finals. By good I mean voltage on control grids must switch from approx -100vdc cut off bias to approx -55vdc operating bias when you flip to Send. This is occurring as you stated you are able to set resting plate current to 60ma.

3. Good RF drive voltage at the control grids of the 6146 finals. By good I mean approx 46rms rf volts. 46 x 1.414 = 65 peak rf volts. +65 and -55 = approx +10 volts on positive peak of the drive envelope. This causes control grid to be positive with respect to the cathode and ! approx 40ua of grid current.

When the control grid of the 6146 final tubes becomes positive with respect to the cathode grid current will flow. When grid current flows the ALC amp transistor senses it and reduces the ALC bus voltage and reduces the RF drive. When the ALC bus voltage is reduced from its nominal 3.2vdc RF-1 level the ALC meter circuit sees this and drives the meter up scale. So with any hint of grid current the ALC meter should move up scale. At approx 40ua of grid current meter should be full scale.

If the Driver tube is soft could have insufficient RF voltage swing at 6146 control grids to overcome the -55vdc bias offset. For example if Driver tube is only capable of 39rms volts then 39 x 1.414 = 55 peak volts. So if RF drive is swinging the control grid to +55 volts on positive going peak of the drive envelope then +55 and -55 means Zero difference voltage and the control grid is not positive with respect to the cathode and there will be no grid current and no ALC indication.

Don:

Your wife needs to talk to my wife. She has set at our dining room table many times with a spare TS830 and headphones on while I was down at the bench modulating a customers rig. She is good at tuning VFO and letting me know if the received audio sounds like me or not.

We have changed seats. I dont like doing it that way as something about a gals voice. OK sorry ladies if you are reading along. I really just worry she will get curious and stick her fingers in that 900vdc!

Terry

Chris,

Remember, all these microphones are getting OLD and many do have bad elements. Also, "on air audio reports" are suspect. Terry or whoever mentioned it is very correct in asking you to check yourself on a monitor receiver. If you have the opportunity, try another microphone. The "treasured" MC-50 you buy may or may not be any better than what you have. I have a shelf full of good looking microphones that sound VERY bad as the elements are shot.

I have the best luck monitoring myself by transmitting into a dummy load and trailing a short piece of any wire along the shelf from the monitor receiver. ALWAYS use headphones when monitoring yourself so you can hear the signal well. Make SURE you are on the same frequency as your transmitting rig (tune through the signal and see if you can hear a "sweet spot").

The next best test is to ask a ham close to you that knows what you sound like "live" to listen and comment. This is still VERY objective, as some like really bassy sound, some like more highs for "clarity". Each will likely give you a different report. You are the chief engineer and have to decide when you sound good to yourself!! Last tip: I often ask my wife of 45 years to put on the headphones and tell me if it sounds like me on the monitor receiver. She knows what I sound like best :>).

Another update. On air reports state my audio sounds distorted. It does sound better with the ATT on my monitor radio, but I am getting bad audio reports from distant stations. I am so bummed. This radio has the nicest receive audio I have ever heard on SSB. I hope I can get this ironed out.

Thanks,

Chris KQ6UP

On Sat, Sep 14, 2013 at 8:10 AM, Chris Maness <chris@...> wrote:

Ok, update. I tried the 160/80/40m with the new driver. I get ALC deflection in TUN finally. I get a peak of about 40% of full scale in 160m. I get 20% of full scale in 80m, and it just barley moves at the DRIVE peak on 40m. Not even a quiver at 20m. So I am thinking my best driver is still on the flat side. I think there is a problem though. I only get deflection when the CAR is set to fully CCW. That makes me think something is broken, and will still be an issue when I get a strong driver tube.

Chris

Ok, I tried a couple of different driver tubes now. With on RCA that appeared to be NOS, I doubled my output power to 20W, but no ALC deflection in tune. With a generic tube I am getting 60W out in CW. However, still no ALC deflection in TUN mode. No matter what the settings. The ALC meter does deflect in USB/LSB. I would say that the meter function seems normal. I get very little power out in SSB, and using a dummy load and my little FT-817 for a monitor, the audio sounds pretty crappy.

Hope this helps the trouble shooting process.

When you say you are getting 10 watts output in SSB mode are you saying when you key the mic in SSB with mic gain turned all the way down you are getting out 10 watts? OR

I am getting 10W peaks. No carrier present. I think I remember aligning the radio when I first got it. It is pretty much working ok, but with low power.

Are you saying while modulating the rig in SSB mode (speaking into the microphone with the mic gain turned up to approx 1200) that you only see about 10 watts on voice peaks?

Yes.

These are two very different things. 10 watts on voice peaks is a little low but it depends on your mic, the mic gain setting, how you are talking in to it and a little with the ballistic characteristics of your wattmeter.

If it is the former then the Balanced Modulator carrier null/balance is probably out of adjustment assuming no problem with the ring diodes. You will need to adjust TC-1 and VR-2 on the Generator board to null and balance the carrier between LSB and USB. Will need RF

probe and VTVM/DMM or O-scope to do this. We can help you perform this step. Another way to do it is with a separate receiver sitting near the 520 but not as sensitive, but probably OK at this po! int to get it close.

Yes, it is balanced. See above.

If it is the later then with rig loaded to 100 watts output it is normal to see peaks of no more than 25 to 30 watts maximum on an average reading wattmeter as you modulate the rig. If you had ALC indication would tell you to adjust mic gain to keep ALC indication within middle of the black rectangular box. Your manual will tell you to keep the peaks within the upper limit of the range. This is to prevent splatter to adjacent frequencies.

Yes, got it. Just like most other SSB rigs.

With the rig in LSB or USB you should be able to key the mic or flip to send and have no RF output power until you speak in the Mic. The Car Level pot has nothing to do with this. It can be set anywhere and have no effect on SSB power output.

Yes, no power unless modulation is present.

When you say your audio is distorted are you saying your transmit audio or receive audio? If transmit then I would perform the carrier null/balance as a first step.

When I increase the mic gain, but this could be the said splatter. I am not going to worry about this until I can get the rig to put out more power and a proper ALC reading.

Yes you can use a DMM but it is not as good for peaking and nulling as an analog meter is. It will work if that is what you have. Also, depending on your DMM it may not be 10meg input and not good for much more than measuring things like dc power supply voltages and some of the tube dc voltages. Not good for getting on grids of tubes and AGC/ALC bus work. A cheap Harbor Freight has an input Z of under 1 meg and some of the Lowes/Sears/Home Depot are around 2meg. They are for electricians and not electronic work.

Got it. For peaking. I had one when I was a teenager. I think I saw it at my parents house. I have not messed with it since the 80's.

Terry K9TW

Thanks,

Chris Maness

--- In ts-520_820_530_830@yahoogroups.com, <chris@...> wrote:

Two more questions. Why would it only put out power in CW when the CAR is fully CCW (0 position)? If I increase it at all I loose all power to the antenna. At full CCW I get 10W out. This seems strange to me. However, under NO conditions do I get an ALC deflection (in TUN or CW). I have not messed with the ALC in SSB. However, I only get about 10W out in SSB too. Audio is also a bit on the crappy side. I suppose loss in linearity of the driver tube could explain the bad audio.

Can I use my modern DVM in place of a VTVM? I might have an oldy at my parent's house if they have not tossed it.

Thanks,

Chris

Chris:

I tried to respond but have not seen it yet so not sure what happened. I dont like this new format. Hard to teach old dog new tricks/.

So let me restate to make sure I fully understand.

You are telling me that you had the SG switch off, the Heaters on, in CW mode, Meter in ALC, the CAR level pot full CW or at minimum no less than at 1200 or No 5 position. When you flip to s! end and peak the Drive control thru its complete range that you get no ALC indication on any band. If that is true then most likely problem is:

Yes, you have understood me correctly I did the test 100% per your instruction. I also did the test as if I was following the tuning procedure to peak the driver as per the manual. I did this in TUN mode. Every single band showed no deflection when the CAR was at 5 and also at 10 (fully CW). I will try to get a hold of a 12BY7A and report back.

Thank you for the flow chart below.

1. Bad 12BY7A driver tube or bad dc voltages to it or bad solder connections at tube socket.

2. Bad/dirty contacts on Aux relay that switches the ALC bus voltage

Hi Terry

Don't know if you keep separate files on posters,but here goes

Were we left off was i had only a bad audio hum and no dial light on my Ebay special.
Update

I now have a good working audio board and dial light display and good audio output from the test's you last asked me to do are now fine
No meter movement,but loud.
The problems are now as follows.
Sidetone fine and good audio
Moni--i can hear it but very very low,,volume turned to full output.
Calibration,can hear it but very very low,,,volume turned to full
On my SG audio good,but only S-3 meter reading.
I can hear 40 meter strong signals at night,but very very low audio.

On transmit,i can only get the 60ma reading and that's it,no output.
All voltages on the finals are fine.
All voltages on the connector's are fine.

Don/Ve2ud

Well Don you are correct. I have slept since last time we talked.

Right now my rigs are all blurring together.

There may be a connection to RF output, but I would concentrate on fixing the receive first. I almost always get the receiver working first.

So what I understand is you have the Audio board working good now. I am not sure what you mean by loud but no meter movement. There will be no meter movement from Side tone or if you inject test audio into the Product detector output to the input of the Audio board. Only way to have S-,meter action is off air or marker signal that comes in front end and down the IF chain.

So trusting that the audio board is working as it should and can process the output of the Product Detector, then the problem now is very weak Marker and very weak off air signals and low or no S-meter indication. Dont worry about weak moni at this point.

So this is place I would use RF sig generator and split the problem. Is it on the IF board or the RF board (or both but not likely). If you want to work back from the Audio Board then I would inject 8.830 mhz into the RIF terminal on the IF board and see if you can hear it loud and good S meter indication. If you can then move on to the RF board. If you cannot get back and we can talk about signal injection/tracing on the IF board.

Inject 8.830mhz at Conn 6 on IF board. You dont need any modulation. -73dBM/50uv should give approx S6. -53dBm/500uv should give approx S9. -33dBm/5mv should give approx +20 over.

On 01/08/2013 8:10 PM, Terry Wagoner wrote:

Don:

The other common thing to look at before you pull the RF board would be VCO signal level and frequency at TP-3 on RF board.

In 40 meter bandswitch position you should have close to 1.0rf volts @ 16mhz (see service manual for frequency vs VFO setting) at TP-3.

VCO is the Local Oscillator (LO) for both the Transmit Mixer and the 1st IF Mixer (RIF). NO VCO = no TX and no RX.

Sounds like both of us have keepers, Terry. I too won't turn mine loose inside the rig AT ALL, even though she is KD5EXI. She does alright with the 2M rig, but that's enough for now. She HAS expressed a desire to learn CW, so we are going to take that on as a winter project sending to each other on 2M (using tone generators into the FM) and will include a friend in the same boat but some distance from us. Otherwise we'd just communicate with the practice oscillators. That will be a challenge, but may help my rusty CW speed some :>). She says she will go for General class if she masters CW enough to use it.

No, guys, mine has no sisters and I'm keeping her another 45 years if we make it that long, HI.

Made these notes a few weeks ago,so i forgot what i meant by loud and no meter movement,,think it was a test you
made me perform a way back on the audio board.
Ok printed that out and back to the bench

You will have all the rest time you want when you depart this world unless you will come back as a Yahoo programmer!

Hi Terry:

Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.

This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.

Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there something else that we should check first?

Thanks,
  Brian (and Jason)

Subject: RE: Re: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

 It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4 RF amps flowing thru the 50 ohm dummy load.

This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.

After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.

Read the very last note in the TS-830 loading procedure. It tells you after they have taught you dip and load you dont have to use it as it isnt best or easiest way to load a Class AB1 linear amp!

It directs you to place meter in RF position and Flip to Send and alternately adjust the plate Load and Tune controls for maximum indicated relative power (RF voltage).

With your wattmeter in line leave your TS830 meter in IP. Now after making that initial plate current dip in Tune mode flip to Send in CW mode and alternately adjust Plate Load and Plate tune controls for approx 100watts output.

Your wattmeter will be far more sensitive to any changes you make than your IP meter. You will quickly be able to find the combination that gives you max rf output power. Take a quick look at IP and it should be close to 225ma. If a little over dont worry about it as 265ma is the real limit.

Lastly, if you are having to increase the Car level at the late stage of tuning you are not setting it high enough in the early Drive control peaking step. There is no reason to have to do this. When you peak the Drive give yourself something to look at. If you peg the ALC meter just reduce the Car level pot to get it off the peg.

If you want more punch in your MC-50, just slide an empty toilet paper roll (or something similar) over the mike end and talk into the other end of the paper roll. Based on past technical analysis, too long of a paper roll (Reynolds foil type paper tube) and your audio will develop a severe punchy hollow sound.

Thanks for advice. Yes I have read somewhere that some folk mask some of the mic side slots, and get improvement.

Like the idea of a single transistor amp built into base. May try this over next few days.

Suppose virtually any low signal NPN will do. maybe 2N2222 would do job.

Thanks

Dave

Dave,

The MC50 is a 'close talk' mike. A couple of inches.

Try taping-over the front half of the side slots for better articulation.

Read previous posts in mic alc topic.

If you feel that you need an external mic amp, experiment and make notes!

I built a one-transistor amp into the base of my MC50. Current draw is <100uA so the 9v battery lasts well over a year.

Terry
Now i remember what i said about loud but no s-meter reading,it is this test i did and now i have redid it with the 8.8830 injection at conn 6
I got S1 meter reading with 500 mv injection in con 6 and same on the RF board con 5 pin 2

Don

So trusting that the audio board is working as it should and can process the output of the Product Detector, then the problem now is very weak Marker and very weak off air signals and low or no S-meter indication. Dont worry about weak moni at this point.

So this is place I would use RF sig generator and split the problem. Is it on the IF board or the RF board (or both but not likely). If you want to work back from the Audio Board then I would inject 8.830 mhz into the RIF terminal on the IF board and see if you can hear it loud and good S meter indication. If you can then move on to the RF board. If you cannot get back and we can talk about signal injection/tracing on the IF board.

Inject 8.830mhz at Conn 6 on IF board. You dont need any modulation. -73dBM/50uv should give approx S6. -53dBm/500uv should give approx S9. -33dBm/5mv should give approx +20 over.

Thanks for responding to my question Terry.
I have the manuals for my TS-820S but not for an 830.
Your opinion on the differences in processor design and Z sensitivity is what I was looking for.
If I had an 830 I would set-up the experiment.

A few years ago I compared two different MC50 mods using FFT / subtraction using MSExcel!
It was easy to see the difference and it was repeatable. Trouble is that I've gone through a couple of computers and lost the FFT software...

Great hobby!
Thanks

Don

I believe you are saying that when you inject 8.830 @500mv from your RF sig gen into the RIF terminal on the IF board you have a loud high frequency tone that you can vary with the audio gain pot (not tunable with the VFO), but the S-meter level is only at S1?

I think we measured RFG at Conn 8 with RF gain pot full CW? It should be 3.6vdc

I think we measured AGC bus voltage at Conn 15? .Need to use nothing less than a 10 meg DMM. It will pull the AGC bus down from 3.6 to close to 3.0vdc or slightly less.

Have you measured these two voltages? Normally if the AGC bus voltage is low the S-meter will be driven up scale with no signal applied unless the S-meter driver circuit is bad.

Have you ever performed the IFT alignment? You can perform the procedure in the maintenance section of the operating manual or the steps in the service manual.

Terry
Now i remember what i said about loud but no s-meter reading,it is this test i did and now i have redid it with the 8.8830 injection at conn 6
I got S1 meter reading with 500 mv injection in con 6 and same on the RF board con 5 pin 2

Don

So trusting that the audio board is working as it should and can process the output of the Product Detector, then the problem now is very weak Marker and very weak off air signals and low or no S-meter indication. Dont worry about weak moni at this point.

So this is place I would use RF sig generator and split the problem. Is it on the IF board or the RF board (or both but not likely). If you want to work back from the Audio Board then I would inject 8.830 mhz into the RIF terminal on the IF board and see if you can hear it loud and good S meter indication. If you can then move on to the RF board. If you cannot get back and we can talk about signal injection/tracing on the IF board.

Inject 8.830mhz at Conn 6 on IF board. You dont need any modulation. -73dBM/50uv should give approx S6. -53dBm/500uv should give approx S9. -33dBm/5mv should give approx +20 over.

You can generally get an IM-18 VTVM for next to nothing (I got mine for
$15) off of E-Bay.

Have you checked with the Goodwill to see if you can buy it back? It
might still be sitting in their stock room waiting to be put on the shelf.

Chris,

You might check with Goodwill, as suggested. The "bigness" of the VTVM you will appreciate in your later years as I do NOW!!! If it's the old Eico (232??) it is a keeper as is the IM-18 that Wes suggested. I like the "under counter" ones Heathkit made so I can mount it to the shelf of the bench!!

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. Same for the Plate Tune capacitor.

If you get time it would be good to see if it loads normal on 15 and 10 meters. I would try loading on all the bands and make a chart of how it behaves. Where does the plate Load cap end up for approx 100 watts output at 200ma Ip.

One other thing you should look at if comfortable is the main RF plate choke and the small VHF choke at a right angle at its base and the rf bypass cap at its base. If these show signs of overheating then will need to be replaced. The by pass cap can actually physically split the case open.

Need to have rig unplugged and let set for awhile to led bleeders discharge the HV filter caps. Then remove PA cage cover. Then connect ground jumper from top of plate choke and ground for a few seconds. Now safe to use a good flashlite and inspect these items.

I would also look at both capacitor shaft couplers at the PA cage and make sure screws are tight. Can also watch the travel and make sure full open and full close align with markings

on the front panel.

Hi Terry:

Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.

This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.

Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there something else that we should check first?

Thanks,
Brian (and Jason)

Subject: RE: Re: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap

and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4 RF amps flowing thru the 50 ohm dummy load.

This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.

After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.

Read the very last note in the TS-830 loading procedure. It tells you after they have taught you dip and load you dont have to use it as it isnt best or easiest way to load a Class AB1 linear amp!

It directs you to place meter in RF position and Flip to Send and alternately adjust the plate Load and Tune controls for maximum indicated relative power (RF voltage).

With your wattmeter in line leave your TS830 meter in IP. Now after making that initial plate current dip in Tune mode flip to Send in CW mode and alternately adjust Plate Load and Plate tune controls for approx 100watts output.

Your wattmeter will be far more sensitive to any changes you make than your IP meter. You will quickly be able to find the combination that gives you max rf output power. Take a quick look at IP and it should be close to 225ma. If a little over dont worry about it as 265ma is the real limit.

Lastly, if you are having to increase the Car level at the late stage of tuning you are not setting it high enough in the early Drive control peaking step. There is no reason to have to do this. When you peak the Drive give yourself something to look at. If you peg the ALC meter just reduce the Car level pot to get it off the peg.

Terry, I just re-read all the emails. There's a lot in there. Thanks for the details.

A couple of things:

I do have some test gear. 1. and Oscilloscope (with probe) and a Frequency counter. I am prepared to make some measurements if you want to walk me through them.

I do somewhat understand the way forward biasing the ring modulator causes it to change its properties from a balanced modulator to an unbalanced one to produce a CW carrier. I am thinking there must be a short or a bad cap/resistor some where in that circuit. I would like to fix this first -- as this would prevent enough carrier to be present in the CW mode. Also, I need to be using a Z matched mic before I start worrying about the audio quality too. I would really like to nail down this CAR issue. I guess its time to pour over the schematic again like I did several years ago.

Thanks a ton Terry,

I believe you are saying that when you inject 8.830 @500mv from your RF sig gen into the RIF terminal on the IF board you have a loud high frequency tone that you can vary with the audio gain pot (not tunable with the VFO), but the S-meter level is only at S1?

I think we measured RFG at Conn 8 with RF gain pot full CW? It should be 3.6vdc

I think we measured AGC bus voltage at Conn 15? .Need to use nothing less than a 10 meg DMM. It will pull the AGC bus down from 3.6 to close to 3.0vdc or slightly less.

Have you measured these two voltages? Normally if the AGC bus voltage is low the S-meter will be driven up scale with no signal applied unless the S-meter driver circuit is bad.

Have you ever performed the IFT alignment? You can perform the procedure in the maintenance section of the operating manual or the steps in the service manual.

See if you can borrow a voltmeter (DMM or VOM) and we can go over measuring the dc voltage at BM terminal on the Gen board for each position of the Car Level pot. Need to make sure you are not immediately getting enough dc bias voltage to turn on the ring diodes and produce a carrier.

If the Car Level pot and its associated circuit is working as it should then I am at a loss as to why you would have instant carrier when just cracking open the Car Level pot.

Is your receive audio clean with no hum on it?

With your scope you could look at the 9vdc regulated off the AVR board to make sure no ripple on it. The Car Level pot needs clean 9vdc applied to it.

OK as I understand what you are saying you are speaking in the mic and getting some flicks of ALC and when you increase the mic gain more you reach a point where you lose the flicks of ALC and as you increase the mic gain past that spot you get flicks but much higher than you would like to see. Is this correct?

Try this to see if you are losing ALC indication or losing modulation.

Flip the meter to Ip or RF and watch the meter as you perform the same increase in mic gain. See if at the same place you were losing ALC you also lose Ip or RF indication. If you do then you know it is likely a bad spot on the mic gain pot. The peaks on IP and RF meter position will be different than what you observed on ALC but dont worry about that.

If so, you lose Ip and RF like you do ALC I would try cleaning the mic gain pot as a first step.

Also what kind of ALC indication are you trying to attain on voice peaks?

What position are you trying to run the Mic gain at (3, 4, 5, 6)?

Chris,

just about any major brand (I prefer US made) should be fine. Check out Ken Kemski's website: k4eaa.com he sells NOS & used drivers
for the KW hybrids at a fair price, and quick service. Mostly it's the "other manufactures" of the 6146's that will cause trouble.
If I may make a suggestion, get 2 driver tubes & a known good set of finals. It can help out down the road with diagnostics.

Chris:

OK then very easy to get that DMM on the BM terminal on the Gen Board and measure what dc voltage you have with the CAR Level pot set at minimum (full CCW). Then monitor and record the dc voltage as you slowly begin to open it (CW).

As I previously cautioned be aware you are working near the HV filter caps and 900vdc. I would set the rig on its side to access BM terminal post.

I previously gave you the voltage levels for each CAR level step.

Yes Deoxit spray and canned air. I also like to use some Deoxit Fader Type F lube after cleaning. It is made for carbon trace pots and it helps maintain good smooth and quiet action for longer time after pot is cleaned. If you dont have any dont worry about it at this time. Just spray and exercise pot thru its full range multiple times and blow out with canned air. Do this with power off.

Don

Use a low level to inject 8.830 at RIF on IF board and couple output of sig gen thru about a .01uf cap. Nothing more than 5 mv. Also, a couple of the cans will have very little effect on signal level on the S-meter as you turn the core. Do not worry about those at this time. If you get some improvement in S-meter indication suggest you lower the sig gen level and make a 2nd pass. What you are looking for is something that has been grossly mis-tuned that will make IF chain come alive.

If doing IFT alignment does not produce significant improvement in Rx sensitivity then I think time to remove the IF board and do good visual inspection on all the molex pins under magnification and look at all the traces for damage and signs of cobbled repairs. Can have lifted pads and traces, solder bridging, wire jumpers, maybe even a blown trace etc.

I am pretty sure I had you measure Carrier Oscillator and VBT Osc previously and you reported they were to spec. I think we also measured all the DC supply voltages to the board.

We have not yet tried injecting signals in to the IF filters and measuring the output to verify filters are good.

We can do signal injection/tracing next to find where the attenuation is occurring or you can pull board and do good visual. If you have already done that then only thing left (assuming that all necessary signals and DC inputs are present on the board) is to do signal injection/tracing.

I have to trust you when you report back that you have the signals and voltages I ask you to check and that you have the test gear to detect and measure these required inputs and know how to use them. I am not there to witness any of these measurements. I can tell you however it is pretty common for me to hear back from someone I am trying to help that previously reported findings were not correct.

I mean no disrespect it is just a pretty common for this to happen.

Terry

Just a follow up before i start

First the RF board i am working on is not the best,as some cans have piece's of elastic bands on them to hold the coil's in place.

I had the RF board all adjusted before the rig when puff,but was not easy to do with the resistance from those rubber bands.Three coils have the rubber band fix,so i need to recheck those coils in case they are part of the problem.

I am on the hunt for another parts radio to replace this RF board as it's cheaper to buy the whole radio.than just the boards.

I have a old Heathkit signal tracer with the green eye,would this be useful

Picked up up a VTVM IM5218 for three bucks at the local hamfest,love the big dial

I have a bid in for a 309c rf probe for it on Ebay.

I also have a Im11 with a good standard probe.

Soon as i finish having my oatmeal i will have a go at it and get back to you

What you are looking for is something that has been grossly mis-tuned that will make IF chain come alive.

If doing IFT alignment does not produce significant improvement in Rx sensitivity then I think time to remove the IF board and do good visual inspection on all the molex pins under magnification and look at all the traces for damage and signs of cobbled repairs. Can have lifted pads and traces, solder bridging, wire jumpers, maybe even a blown trace etc.

I am pretty sure I had you measure Carrier Oscillator and VBT Osc previously and you reported they were to spec. I think we also measured all the DC supply voltages to the board.

We have not yet tried injecting signals in to the IF filters and measuring the output to verify filters are good.

We can do signal injection/tracing next to find where the attenuation is occurring or you can pull board and do good visual. If you have already done that then only thing left (assuming that all necessary signals and DC inputs are present on the board) is to do signal injection/tracing.

I have to trust you when you report back that you have the signals and voltages I ask you to check and that you have the test gear to detect and measure these required inputs and know how to use them. I am not there to witness any of these measurements. I can tell you however it is pretty common for me to hear back from someone I am trying to help that previously reported findings were not correct.

I mean no disrespect it is just a pretty common for this to happen.

I believe you are saying that when you inject 8.830 @500mv from your RF sig gen into the RIF terminal on the IF board you have a loud high frequency tone that you can vary with the audio gain pot (not tunable with the VFO), but the S-meter level is only at S1?

I think we measured RFG at Conn 8 with RF gain pot full CW? It should be 3.6vdc

I think we measured AGC bus voltage at Conn 15? .Need to use nothing less than a 10 meg DMM. It will pull the AGC bus down from 3.6 to close to 3.0vdc or slightly less.

Have you measured these two voltages? Normally if the AGC bus voltage is low the S-meter will be driven up scale with no signal applied unless the S-meter driver circuit is bad.

Have you ever performed the IFT alignment? You can perform the procedure in the maintenance section of the operating manual or the steps in the service manual.

Now i remember what i said about loud but no s-meter reading,it is this test i did and now i have redid it with the 8.8830 injection at conn 6
I got S1 meter reading with 500 mv injection in con 6 and same on the RF board con 5 pin 2

Don

So trusting that the audio board is working as it should and can process the output of the Product Detector, then the problem now is very weak Marker and very weak off air signals and low or no S-meter indication. Dont worry about weak moni at this point.

So this is place I would use RF sig generator and split the problem. Is it on the IF board or the RF board (or both but not likely). If you want to work back from the Audio Board then I would inject 8.830 mhz into the RIF terminal on the IF board and see if you can hear it loud and good S meter indication. If you can then move on to the RF board. If you cannot get back and we can talk about signal injection/tracing on the IF board.

Inject 8.830mhz at Conn 6 on IF board. You dont need any modulation. -73dBM/50uv should give approx S6. -53dBm/500uv should give approx S9. -33dBm/5mv should give approx +20 over.

44566. Examples of basic test equipment

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

Topic: 44566 Message: 44566

Good morning everyone,

This morning I made a video showing some very basic test equipment for your shack. Although most of the test equipment shown in the video is Heathkit, anymake/model would serve the same purpose. The video is located at:

www.n6wk.com/w5rkl/basic test equipment/ folder

Take a few minutes and view the video. The video is 69.5meg so it may take a few minutes to load. Windows Media Player works fine with all my videos.

For those who have never used any test equipment before when servicing electronic equipment, I recommend start with basic test equipment first. Once you are comfortable using the basic equipment the move to more advanced/modern test equipment.

I still use all of the test equipment shown in the video. An example of how effective the old IG-102 signal generator can be, I used italong with the IM-4100 frequency counter to troubleshoot a Kenwood TS-120 that had no receive and no transmit, the digital display had only decimal points displayed. That told me the PLL Unit had changed to an "Unlocked" state. The IM-4100 was used to look for various oscillator signals applied to the PLL Unit. All were there except the 8Mhz signal. I used the IG-102 as a substitute for the 8Mhz oscillator, fed the IG-102 signal to the PLL Unit and BINGO the 120 came to life! I also used the same signal generator to troubleshoot a Collins 75A2 receiverto track down a failed PTO(VFO). I used the same technique of substituting the PTO with the IG-102. Just because the test gear shown in the video is old does not mean it cannot be used to service your hybrid. You just have to learn how to use it properly.

Don:

Do you mean IF board and not RF board? Bad RF board has nothing to do with weak signal when you are subing the RIF signal into the IF board.

Bob Mansker sells good IF boards pretty reasonably. Ihave purchased several from him. RF boards require 2nd mortgage from any supplier.

I have never had any luck at scoring what I would call a bargain tech special rig. Most I see on ebay never go for less than around $200 so with shipping looking at $250 for a parts rig. I have gotten couple of parts rig when the customers poorly packed the rig and sent it to me for repair and it was severely damaged in shipping. Able to buy them for cost of shipping. Dont like to get them that way.

Terry

Just a follow up before i start

First the RF board i am working on is not the best,as some cans have piece's of elastic bands on them to hold the coil's in place.

I had the RF board all adjusted before the rig when puff,but was not easy to do with the resistance from those rubber bands.Three coils have the rubber band fix,so i need to recheck those coils in case they are part of the problem.

I am on the hunt for another parts radio to replace this RF board as it's cheaper to buy the whole radio.than just the boards.

I have a old Heathkit signal tracer with the green eye,would this be useful

Picked up up a VTVM IM5218 for three bucks at the local hamfest,love the big dial

I have a bid in for a 309c rf probe for it on Ebay.

I also have a Im11 with a good standard probe.

Soon as i finish having my oatmeal i will have a go at it and get back to you

Use a low level to inject 8.830 at RIF on IF board and couple output of sig gen thru about a .01uf cap. Nothing more than 5 mv. Also, a couple of the cans will have very little effect on signal level on the S-meter as you turn the core. Do not worry about those at this time. If you get some improvement in S-meter indication suggest you lower the sig gen level and make a 2nd pass. What you are looking for is something that has been grossly mis-tuned that will make IF chain come alive.

If doing IFT alignment does not produce significant improvement in Rx sensitivity then I think time to remove the IF board and do good visual inspection on all the molex pins under magnification and look at all the traces for damage and signs of cobbled repairs. It appears the link to my videos on Gordon's website, for some unknown reason, don't work.

Try any of the following 3 links. I've tested all 3 of them and they work.

http://www.n6wk.com/w5rkl/

www.n6wk.com/w5rkl/

or

n6wk.com/w5rkl/

and hit ENTER.

Mike
SeaMonkey browser says could not locate specified clip,and Firefox says
the same
Google Chrome says attempting to play an extension [tmp] that does
not match file format.
Then say's do you want player to play this format...say yes,and then it
plays fine.

Terry
Bob wants $110 plus shipping and there is a exchange rate on top of that
That would be close to $130

I paid $90 for the that last rig that i was able to fix,,yes don't get deals like that everyday.
I will keep searching as i have learn't a long time ago in life that there is always another one

Don:

Do you mean IF board and not RF board? Bad RF board has nothing to do with weak signal when you are subing the RIF signal into the IF board.

Bob Mansker sells good IF boards pretty reasonably. Ihave purchased several from him. RF boards require 2nd mortgage from any supplier.

I have never had any luck at scoring what I would call a bargain tech special rig. Most I see on ebay never go for less than around $200 so with shipping looking at $250 for a parts rig. I have gotten couple of parts rig when the customers poorly packed the rig and sent it to me for repair and it was severely damaged in shipping. Able to buy them for cost of shipping. Dont like to get them that way.

Just a follow up before i start

First the RF board i am working on is not the best,as some cans have piece's of elastic bands on them to hold the coil's in place.

I had the RF board all adjusted before the rig when puff,but was not easy to do with the resistance from those rubber bands.Three coils have the rubber band fix,so i need to recheck those coils in case they are part of the problem.

I am on the hunt for another parts radio to replace this RF board as it's cheaper to buy the whole radio.than just the boards.

I have a old Heathkit signal tracer with the green eye,would this be useful

Picked up up a VTVM IM5218 for three bucks at the local hamfest,love the big dial

I have a bid in for a 309c rf probe for it on Ebay.

I also have a Im11 with a good standard probe.

Soon as i finish having my oatmeal i will have a go at it and get back to you

Use a low level to inject 8.830 at RIF on IF board and couple output of sig gen thru about a .01uf cap. Nothing more than 5 mv. Also, a couple of the cans will have very little effect on signal level on the S-meter as you turn the core. Do not worry about those at this time. If you get some improvement in S-meter indication suggest you lower the sig gen level and make a 2nd pass. What you are looking for is something that has been grossly mis-tuned that will make IF chain come alive.

If doing IFT alignment does not produce significant improvement in Rx sensitivity then I think time to remove the IF board and do good visual inspection on all the molex pins under magnification and look at all the traces for damage and signs of cobbled repairs. Can have lifted pads and traces, solder bridging, wire jumpers, maybe even a blown trace etc.

I am pretty sure I had you measure Carrier Oscillator and VBT Osc previously and you reported they were to spec. I think we also measured all the DC supply voltages to the board.

We have not yet tried injecting signals in to the IF filters and measuring the output to verify filters are good.

We can do signal injection/tracing next to find where the attenuation is occurring or you can pull board and do good visual. If you have already done that then only thing left (assuming that all necessary signals and DC inputs are present on the board) is to do signal injection/tracing.

I have to trust you when you report back that you have the signals and voltages I ask you to check and that you have the test gear to detect and measure these required inputs and know how to use them. I am not there to witness any of these measurements. I can tell you however it is pretty common for me to hear back from someone I am trying to help that previously reported findings were not correct.

I mean no disrespect it is just a pretty common for this to happen.

I believe you are saying that when you inject 8.830 @500mv from your RF sig gen into the RIF terminal on the IF board you have a loud high frequency tone that you can vary with the audio gain pot (not tunable with the VFO), but the S-meter level is only at S1?

I think we measured RFG at Conn 8 with RF gain pot full CW? It should be 3.6vdc

I think we measured AGC bus voltage at Conn 15? .Need to use nothing less than a 10 meg DMM. It will pull the AGC bus down from 3.6 to close to 3.0vdc or slightly less.

Have you measured these two voltages? Normally if the AGC bus voltage is low the S-meter will be driven up scale with no signal applied unless the S-meter driver circuit is bad.

Have you ever performed the IFT alignment? You can perform the procedure in the maintenance section of the operating manual or the steps in the service manual.

Terry K9TW

Now i remember what i said about loud but no s-meter reading,it is this test i did and now i have redid it with the 8.8830 injection at conn 6
I got S1 meter reading with 500 mv injection in con 6 and same on the RF board con 5 pin 2

Don

So trusting that the audio board is working as it should and can process the output of the Product Detector, then the problem now is very weak Marker and very weak off air signals and low or no S-meter indication. Dont worry about weak moni at this point.

So this is place I would use RF sig generator and split the problem. Is it on the IF board or the RF board (or both but not likely). If you want to work back from the Audio Board then I would inject 8.830 mhz into the RIF terminal on the IF board and see if you can hear it loud and good S meter indication. If you can then move on to the RF board. If you cannot get back and we can talk about signal injection/tracing on the IF board.

Inject 8.830mhz at Conn 6 on IF board. You dont need any modulation. -73dBM/50uv should give approx S6. -53dBm/500uv should give approx S9. -33dBm/5mv should give approx +20 over.
